(57) **ABSTRACT**

A liquid crystal panel (10) includes an active matrix substrate on which a transistor (12), a pixel electrode (17), signal lines (15, 16) and backup wirings (8a, 8b) for recovering a defect in the signal line are formed; a color filter substrate on which a common electrode (counter electrode) is formed; and a liquid crystal material provided between the active matrix substrate and the color filter substrate. The backup wirings (8a, 8b) are (electrically) connected to the common electrode on the color filter substrate, through (i) a protection circuit (9) for discharging an undesired electric charge that occurs in the backup wirings (8a, 8b) and (ii) a sealing adhesive (6). With this configuration, it becomes possible to reduce problems (for instance, unexpected short-circuiting of the backup wiring and the signal line) caused by the undesired electric charge that occurs in the backup wirings.

LIQUID CRYSTAL PANEL, LIQUID CRYSTAL DISPLAY APPARATUS AND TELEVISION RECEIVER

This application is the U.S. national phase of International Application No. PCT/JP2008/050260 filed 11 Jan. 2008, which designated the U.S. and claims priority to Japan Application No. 2007-006278 filed 15 Jan. 2007, the entire contents of each of which are hereby incorporated by reference.

TECHNICAL FIELD

The present invention relates to a backup wiring provided in a liquid crystal panel.

BACKGROUND ART

FIG. 9 is a plan view illustrating a configuration of a conventional liquid crystal display. As shown in FIG. 9, a liquid crystal panel 110 includes: an active matrix substrate 103; a color filter substrate (not illustrated); a sealing adhesive 106 for bonding the active matrix substrate 103 and the color filter substrate; and a liquid crystal material (not illustrated) that fills a space enclosed by the active matrix substrate 103, the color filter substrate, and the sealing adhesive 106.

The active matrix substrate 103 includes: a plurality of scanning signal lines 116 and a plurality of data signal lines 115 which are arranged crisscross; a TFT 112 (Thin Film Transistor) formed in the vicinity of each intersection of the signal lines (115, 116); and a pixel electrode 117. The TFT 112 has: a gate electrode that is connected to a scanning signal line 116; a source electrode that is connected to a data signal line 115; and a drain electrode that is connected to the pixel electrode 117. Further, on the color filter which is not illustrated, a common electrode is formed so as to be opposed to the pixel electrode 117 via the liquid crystal material.

In the liquid crystal panel 110, a data signal (signal potential) having been transmitted to the data signal line 115 is written to the pixel electrode 117 through the TFT 112. This causes a potential difference between the pixel electrode 117 and the common electrode (on the color filter substrate). This potential difference controls an optical transmittance of the liquid crystal material.

A retention capacitor wiring (Cs wiring) 118 has such functions as (i) preventing self-discharge of the liquid crystal material during an off period of the TFT 112 and (ii) providing each pixel with a modulation signal. The retention capacitor wiring 118 is connected to a major retention capacitor wiring 107 in a nondisplay area 155.

As shown in FIG. 9, backup wirings 108 run from the vicinity of (on an inner side of) one side (a side along the scanning signal line 116) that forms an outside edge of the liquid crystal panel 110 and extend, through an external substrate or the like, up to positions on an outer side of another side (another side along the scanning signal line 116) opposite to the aforesaid one side. The backup wirings 108 are used for recovering disconnection or the like of, for example, the data signal line 115.

If an undesired large electric charge occurs in the backup wiring due to static electricity or the like, a failure in wiring (e.g., short-circuiting of the backup wiring 108 and the data signal line 115) may occur, for example, at an intersection C of the backup wiring 108 and the data signal line 115. To counter this problem, as shown in FIG. 10, the liquid crystal panel 110 has such a configuration that the backup wirings 108 are connected, through a protection circuit 109, to the major retention capacitor wiring 107 and to a floating island

electrode 111 (a light blocking metal in the nondisplay area 155) (refer to Patent Literature 1).

SUMMARY OF THE INVENTION

However, since being electrically isolated, a floating island electrode can absorb only a limited amount of electric charge. Under this circumstance, a case where a large electric charge occurs in a backup wiring may result in a problem such as a breakdown of a protection circuit and a failure in wiring as described above.

The present invention is attained in view of the above problem and an object of the present invention is to provide a liquid crystal panel in which a failure in wiring is less likely to occur even if an undesired large electric charge occurs in a backup wiring due to static electricity or the like.

The liquid crystal panel of the present invention includes: a first substrate on which a switching element, a pixel electrode, a signal line, and a backup wiring for recovering a defect in the signal line are formed; a second substrate being opposed to the first substrate, on which second substrate a common electrode is formed; and a liquid crystal material provided between the first substrate and the second substrate, the backup wiring being electrically connected to the common electrode through a protection circuit for discharging an undesired electric charge that occurs in the backup wiring.

Further, the liquid crystal panel of the present invention including: a first substrate on which a switching element, a pixel electrode, and a signal line are formed; a second substrate being opposed to the first substrate, on which second substrate a common electrode is formed; and a liquid crystal material provided between the first substrate and the second substrate, the liquid crystal panel includes: a backup wiring for recovering a defect in the signal line; and a protection circuit for electrically connecting the backup wiring to the common electrode when a potential of the backup wiring exceeds a threshold value.

In this configuration, if an undesired large electric charge occurs in the backup wiring due to static electricity or the like, the backup wiring will be electrically connected to the common electrode on the second substrate through the protection circuit. Accordingly, the electric charge can be discharged to the common electrode. This makes it possible to reduce problems (for example, unexpected short-circuiting of the backup wiring and the signal line) caused by the undesired electric charge that occurs in the backup wiring.

The liquid crystal panel of the present invention is preferably configured such that the protection circuit is provided on the first substrate; the first substrate and the second substrate are bonded with a sealing adhesive containing a conductive body, and the conductive body is electrically connected to the protection circuit and to the common electrode. This configuration makes it easy to electrically connect the first and second substrates.

The liquid crystal panel of the present invention may be configured such that the protection circuit contains a semiconductor element that allows a current to flow only when a potential of the backup wiring exceeds a threshold value. This configuration makes it possible to easily achieve a protection circuit that (electrically) connects the backup wiring to the

common electrode only when an undesired large electric charge occurs in the backup wiring.

The liquid crystal panel of the present invention may be configured such that the first substrate includes a floating island electrode in a nondisplay area; and the floating island electrode is electrically connected to the protection circuit and to the conductive body. This configuration makes it easy to connect the protection circuit and the conductive body that is contained in the sealing adhesive.

The liquid crystal panel of the present invention may be configured such that the first substrate includes a connection electrode in contact with the sealing adhesive; and the sealing adhesive is in contact with the common electrode on the second substrate and the connection electrode is in contact with the floating island electrode.

The liquid crystal panel of the present invention may be configured such that the first substrate includes a plurality of backup wirings formed side by side; the protection circuit includes a plurality of current controlling circuits; two backup wirings adjacent to each other are electrically connected with each other through a current controlling circuit; and one of the two backup wirings provided on an outer side is electrically connected to the common electrode through the current controlling circuit. This configuration makes it possible to connect each of the plurality of backup wirings to the common electrode through the protection circuit.

The liquid crystal panel of the present invention may further include: a plurality of retention capacitor wirings running through a display area; and a major retention capacitor wiring being connected with the plurality of retention capacitor wirings in a nondisplay area, wherein the other one of the two backup wirings provided on the outer side is electrically connected to the major retention capacitor wiring through another current controlling circuit. This configuration makes it possible to provide two pathways (a pathway to the common electrode and a pathway to the major retention capacitor wiring) through which an electric charge is discharged. As a result, an undesired electric charge caused by static electricity or the like can be quickly discharged.

Further, the liquid crystal panel of the present invention may be configured such that each of the plurality of current controlling circuits is formed from a first transistor and a second transistor; and a source of the first transistor, a gate of the first transistor, and a drain of the second transistor are electrically connected to the one backup wiring or the other backup wiring or to the common electrode, whereas a source of the second transistor, a gate of the second transistor, and a drain of the first transistor are electrically connected to the one backup wiring or the other backup wiring or to the major retention capacitor wiring.

It is preferable that the floating island electrode also function as a light-shielding material in the nondisplay area.

Further, it is preferable that the conductive body contained in the sealing adhesive be a bead whose surface is coated with a conductive film.

The liquid crystal panel of the present invention may be configured such that the floating island electrode and the connection electrode are in contact with each other in a contact hole that is formed so as to penetrate through an insulating layer of the first substrate. This configuration makes it easy to connect the protection circuit and the conductive body that is contained in the sealing adhesive. In this case, the backup wiring may be provided in a same layer as a scanning signal line which is one of the signal lines, and the connection electrode may be formed in a same layer as the pixel electrode. This configuration makes it possible to form the scanning signal line and the backup wiring in one process concurrently.

Further, the pixel electrode and the connection electrode can be formed in one process concurrently.

The liquid crystal panel of the present invention may be configured such that the first substrate is an active matrix substrate, and the second substrate is a color filter substrate.

The liquid crystal display apparatus of the present invention includes the liquid crystal panel as described above.

The television receiver of the present invention includes: the liquid crystal display apparatus as set forth above; and a tuner section for receiving television broadcast.

As described above, in the liquid crystal panel of the present invention, if an undesired large electric charge occurs in the backup wiring due to static electricity or the like, the backup wiring will be electrically connected to the common electrode on the second substrate through the protection circuit. Consequently, the electric charge can be discharged to the common electrode. This makes it possible to reduce problems (for example, unexpected short-circuiting of the backup wiring and the signal line) caused by the undesired electric charge that occurs in the backup wiring.

DESCRIPTION OF EMBODIMENTS

One embodiment of the present invention is described below with reference to FIGS. 1 to 8.

FIG. 1 is a plan view illustrating a configuration of a liquid crystal panel of the present invention. FIG. 2 is a cross-sectional view taken along a line A-B in FIG. 1.

As shown in FIGS. 1 and 2, the liquid crystal panel 10 includes: an active matrix substrate 3; a color filter substrate 30; a liquid crystal material 40 provided between the active matrix substrate 3 and the color filter substrate 30; and a sealing adhesive 6 for bonding the active matrix substrate 3 and the color filter substrate 30 as well as sealing in the liquid crystal material 40 between the active matrix substrate 3 and the color filter substrate 30.

The active matrix substrate 3 includes: a plurality of scanning signal lines 16 and a plurality of data signal lines 15 which are arranged crisscross; a TFT 12 (switching element) formed in the vicinity of each intersection of the signal lines (15, 16); and pixel electrodes 17. The TFT 12 has: a gate electrode that is connected to the scanning signal line 16; a source electrode that is connected to the data signal line 15; and a drain electrode that is connected to the pixel electrode 17.

The color filter substrate 30 includes: a colored layer which is not illustrated; a common electrode (counter electrode, not illustrated) provided in a display area so as to be opposed to the pixel electrode 17 via the liquid crystal material 40; and a common electrode 27 provided in a nondisplay area (refer to FIG. 2) so as to be electrically connected to the common electrode in the display area. These common electrodes are supplied with common potential. This common potential is kept substantially at a constant level.

In the liquid crystal panel 10, a data signal (signal potential) having been transferred to the data signal line 15 is written to the pixel electrode 17 through the TFT 12. This causes a potential difference between the pixel electrode 17 and the common electrode in the display area (the common electrode formed on the color filter substrate 30). This potential difference controls an optical transmittance of the liquid crystal material 40.

A retention capacitor wiring (Cs wiring) 18 has such functions as (i) preventing self-discharge of the liquid crystal material 40 or providing each pixel with a modulation signal during an OFF period of the TFT 12. The retention capacitor wiring 18 is connected to a major retention capacitor wiring 7 in the nondisplay area 55. It should be noted that, in a case where the liquid crystal panel 10 employs a divided-pixel system (that controls a plurality of subpixels provided in one pixel so that each of the plurality of subpixels has a different luminance from one another and that performs halftone display according to area coverage modulation of the subpixels each having a different luminance), the retention capacitor

wiring 18 is supplied with a Cs signal. The retention capacitor wirings 18 having the same Cs signal phase are connected to the same major retention capacitor wiring 7. In the divided-pixel system, one pixel is provided with a plurality of pixel electrodes 17, each of which individually forms the retention capacitor wiring 18 and a retention capacitor.

As shown in FIG. 1, the backup wirings 8a and 8b run from the non-display area on an inner side of one side (along the scanning signal line 16) that forms an outside edge of the liquid crystal panel 10 and extend up to positions on an outer side of another side (another side along the scanning signal line 16) opposite to the aforesaid one side, through an external substrate or the like. The backup wirings 8a and 8b are used for recovering disconnection or the like of, for example, the data signal line 15. For example, as shown in FIG. 7, in the case where disconnection of the data signal line 15 occurs in the display area, the data signal line 15 is melt-connected to the backup wiring 8a at a preceding point and a subsequent point with respect to a point of the disconnection of the data signal line 15. This makes it possible to supply a signal potential to a section subsequent to the point of disconnection of the data signal line 15.

In the liquid crystal panel 10, each of the backup wirings 8a and 8b is electrically connected through a protection circuit 9 to the major retention capacitor wiring 7 and to the common electrode 27 on the color filter substrate 30 (refer to FIGS. 1 and 2). This configuration is for quickly discharging, outside the backup wirings, an undesired large electric charge that occurs in the backup wirings 8a and 8b due to static electricity or the like. This configuration is described in detail below.

As shown in FIG. 3, the protection circuit 9 includes three current controlling circuits (diode rings) 9a to 9c. Each of the current controlling circuits is configured by connecting two diode elements in inverse directions in parallel with each other. That is, the current controlling circuit 9a is configured by connecting diode elements 5a and 6a in inverse directions in parallel with each other. Further, the current controlling circuit 9b is configured by connecting diode elements 5b and 6b in inverse directions in parallel with each other, and the current controlling circuit 9c is configured by connecting diode elements 5c and 6c in inverse directions in parallel with each other.

Then, in the current controlling circuit 9a, a cathode of the diode element 5a and an anode of the diode element 6a are connected to the major retention capacitor wiring 7, whereas an anode of the diode element 5a and a cathode of the diode element 6a are connected to the backup wiring 8a. In the current controlling circuit 9b, a cathode of the diode element 5b and an anode of the diode element 6b are connected to the backup wiring 8a, whereas an anode of the diode element 5b and a cathode of the diode element 6b are connected to the backup wiring 8b. In the current controlling circuit 9c, a cathode of the diode element 5c and an anode of the diode element 6c are connected to the backup wiring 8b, whereas an anode of the diode element 5c and a cathode of the diode element 6c are connected to the common electrode 27 of the color filter substrate 30.

FIG. 4 shows one specific example of the current controlling circuits (diode rings) 9a to 9c. As shown in FIG. 4, the diode element 5a is configured such that a source and a gate of a transistor T1 (first transistor) are connected with each other to form the anode, while a drain of the transistor T1 serves as the cathode. The diode element 6a is configured such that a source and a gate of a transistor T2 (second transistor) are connected with each other to form the anode, while a drain of the transistor T2 serves as the cathode. The

diode elements **5b** and **5c**, and the diode elements **6b** and **6c** are configured in the same manner.

As a result, the source of the transistor **T1** (first transistor), the gate of the transistor **T1**, and the drain of the transistor **T2** (second transistor) are connected to the backup wiring **8a**, whereas the source of the transistor **T2**, the gate of the transistor **T2**, and the drain of the transistor **T1** are connected to the major retention capacitor wiring **7**. Similarly, a source of a transistor **T3** (first transistor), a gate of the transistor **T3**, and a drain of a transistor **T4** (second transistor) are connected to the backup wiring **8b**, whereas a source of the transistor **T4** (second transistor), a gate of the transistor **T4**, and a drain of the transistor **T3** are connected to the backup wiring **8a**. Further, a source of a transistor **T5** (first transistor), a gate of the transistor **T5**, and a drain of a transistor **T6** (second transistor) are connected to the common electrode **27**, whereas a source of the transistor **T6** (second transistor), a gate of the transistor **T6**, and a drain of the transistor **T5** are connected to the backup wiring **8b**.

Each of the backup wirings **8a** and **8b** is connected to the major retention capacitor wiring **7** and to the common electrode **27** through the protection circuit **9** in the above described manner. In this configuration, if a large electric charge occurs in the backup wiring **8a** due to static electricity or the like, it is possible to discharge the electric charge to the common electrode **27** through the diode elements **6b** and **6c** as well as to the major retention capacitor wiring **7** through the diode element **5a** (refer to FIG. **5**). Similarly, if a large electric charge occurs in the backup wiring **8b** due to static electricity or the like, it is possible to discharge the electric charge to the major retention capacitor wiring **7** through the diode elements **5b** and **5a** as well as to the common electrode **27** through the diode element **6c** (refer to FIG. **6**).

Now, refer back to FIGS. **1** and **2**. The protection circuit **9** is connected to a floating island electrode **11**. The floating island electrode **11** is formed as a light blocking metal, in the nondisplay area of the active matrix substrate **3**. The floating island electrode **11** is formed in the same layer as the scanning signal line **16**. Provided on top of the floating island electrode **1** are a gate insulating film **21** and an interlayer insulating film **25**. Further, a connection electrode **14** is formed on top of the interlayer insulating film **25**. The connection electrode **14** is an ITO electrode that is formed in the same layer as the pixel electrode **17**. This connection electrode **14** is connected with the floating island electrode **11** through a contact hole **33**.

In the liquid crystal panel **10** of the present invention, the sealing adhesive **6** contains a conductive bead **28** having a diameter larger than a size of a cell gap. This conductive bead **28** is provided so as to overlap with the connection electrode **14**. This allows the connection electrode **14** to be electrically connected to the common electrode **27** on the color filter substrate **30** through the conductive bead **28**. More specifically, the sealing adhesive **6** (the conductive bead **28** contained in the sealing adhesive) is in contact with the common electrode **27** on the color filter substrate **30**. Further, the connection electrode **14** is in contact with the sealing adhesive **6** (the conductive bead **28** contained in the sealing adhesive) and with the floating island electrode **11**. Further, as described above, the common electrode **27** (the common electrode in the nondisplay area) is connected to the common electrode (counter electrode) in the display area. In other words, the backup wirings **8a** and **8b** are electrically connected to the common electrode in the display area through the floating island electrode **11**, the connection electrode **14**, the conductive bead **28**, and the common electrode **27**.

The conductive bead **28** contained in the sealing adhesive **6** may be a bead whose surface is coated with a conductive film (e.g., a film made of gold or carbon).

As described above, according to the liquid crystal panel **10** of the present invention, if an undesired large electric charge occurs in the backup wirings **8a** and **8b** due to static electricity or the like (if a potential of the backup wirings **8a** and **8b** exceeds a threshold value of the protection circuit), the backup wirings **8a** and **8b** are electrically connected, through the protection circuit **9**, to the common electrode **27** on the color filter substrate **30** and to the major retention capacitor wiring **7** on the active matrix substrate **3**. As a result, it becomes possible to discharge the electric charge to the common electrode **27** and to the major retention capacitor wiring **7**. This makes it possible to prevent a failure in wiring (for example, short-circuiting or leak in the backup wiring and the data signal line due to static electricity).

As shown in FIG. **8**, the liquid crystal display apparatus according to the present embodiment includes: the liquid crystal panel **10**; a gate driver **65** and a source driver **66** which are for driving the liquid crystal panel **10**; and a controlling device **75** for controlling each of the drivers (**65**, **66**). A television receiver (liquid crystal television) **80** according to the present embodiment includes: the liquid crystal display apparatus **20** of the present invention; and a tuner section **70** for receiving television broadcast so as to output a video signal. That is, in the television receiver **80**, the liquid crystal display apparatus **20** displays a video picture (image) according to the video signal outputted from the tuner section **70**.

The present invention is not limited to the description of the embodiments above, but may be altered within the scope of the claims. An embodiment based on a proper combination of technical means disclosed in different embodiments is encompassed in the technical scope of the invention.

INDUSTRIAL APPLICABILITY

The liquid crystal panel and the liquid crystal display apparatus of the present invention are suitably applicable for, for example, a liquid crystal television.

The invention claimed is:

1. A liquid crystal panel comprising:

a first substrate on which a switching element, a pixel electrode, a signal line, and a backup wiring for recovering a defect in the signal line are formed;

a second substrate being opposed to the first substrate, on which second substrate a common electrode is formed; and

a liquid crystal material provided between the first substrate and the second substrate,

the backup wiring being electrically connected to both the common electrode and a retention capacitor wiring through a protection circuit for discharging an undesired electric charge that occurs in the backup wiring.

2. The liquid crystal panel according to claim 1, wherein: the protection circuit is provided on the first substrate; the first substrate and the second substrate are bonded with a sealing adhesive containing a conductive body; and the conductive body is electrically connected to the protection circuit and to the common electrode.

3. The liquid crystal panel according to claim 2, wherein: the first substrate includes a floating island electrode in a nondisplay area; and the floating island electrode is electrically connected to the protection circuit and to the conductive body.

4. The liquid crystal panel according to claim 3, wherein the floating island electrode also functions as a light-shielding material in the nondisplay area.

5. The liquid crystal panel according to claim 2, wherein the conductive body is a bead whose surface is coated with a conductive film.

6. The liquid crystal panel according to claim 1, wherein the protection circuit contains a semiconductor element that allows a current to flow only when a potential of the backup wiring exceeds a threshold value.

7. The liquid crystal panel according to claim 1, wherein: the first substrate includes a plurality of backup wirings formed side by side;

the protection circuit includes a plurality of current controlling circuits;

two backup wirings adjacent to each other are electrically connected with each other through a current controlling circuit; and

one of the two backup wirings provided on an outer side is electrically connected to the common electrode through the current controlling circuit.

8. The liquid crystal panel according to claim 1, wherein the first substrate is an active matrix substrate, and the second substrate is a color filter substrate.

9. A liquid crystal display apparatus comprising a liquid crystal panel as set forth in claim 1.

10. A television receiver comprising:

a liquid crystal display apparatus as set forth in claim 9; and a tuner section for receiving television broadcast.

11. A liquid crystal panel comprising:

a first substrate on which a switching element, a pixel electrode, a signal line, and a backup wiring for recovering a defect in the signal line are formed;

a second substrate being opposed to the first substrate, on which second substrate a common electrode is formed; a liquid crystal material provided between the first substrate and the second substrate,

the backup wiring being electrically connected to the common electrode through a protection circuit for discharging an undesired electric charge that occurs in the backup wiring;

the protection circuit is provided on the first substrate;

the first substrate and the second substrate are bonded with a sealing adhesive comprising a conductive body;

the conductive body is electrically connected to the protection circuit and to the common electrode;

the first substrate includes a floating island electrode in a nondisplay area;

the floating island electrode is electrically connected to the protection circuit and to the conductive body;

the first substrate includes a connection electrode in contact with the sealing adhesive; and

the sealing adhesive is in contact with the common electrode on the second substrate and the connection electrode is in contact with the floating island electrode.

12. The liquid crystal panel according to claim 11, wherein the floating island electrode and the connection electrode are in contact with each other in a contact hole.

13. The liquid crystal panel according to claim 12, wherein the backup wiring is provided in a same layer as a scanning signal line which is one of the signal lines, and the connection electrode is formed in a same layer as the pixel electrode.

14. A liquid crystal panel comprising:

a first substrate on which a switching element, a pixel electrode, a signal line, and a backup wiring for recovering a defect in the signal line are formed;

a second substrate being opposed to the first substrate, on which second substrate a common electrode is formed;

a liquid crystal material provided between the first substrate and the second substrate,

the backup wiring being electrically connected to the common electrode through a protection circuit for discharging an undesired electric charge that occurs in the backup wiring;

the first substrate includes a plurality of backup wirings formed side by side;

the protection circuit includes a plurality of current controlling circuits;

two backup wirings adjacent to each other are electrically connected with each other through a current controlling circuit;

one of the two backup wirings provided on an outer side is electrically connected to the common electrode through the current controlling circuit;

a plurality of retention capacitor wirings running through a display area;

a major retention capacitor wiring being connected with the plurality of retention capacitor wirings in a nondisplay area,

wherein the other one of the two backup wirings provided on the outer side is electrically connected to the major retention capacitor wiring through another current controlling circuit.

15. A liquid crystal panel according to claim 14, wherein: each of the plurality of current controlling circuits is formed from a first transistor and a second transistor, and a source of the first transistor, a gate of the first transistor, and a drain of the second transistor are electrically connected to the one backup wiring or the other backup wiring or to the common electrode, whereas a source of the second transistor, a gate of the second transistor, and a drain of the first transistor are electrically connected to the one backup wiring or the other backup wiring or to the major retention capacitor wiring.

16. A liquid crystal panel comprising:

a first substrate on which a switching element, a pixel electrode, and a signal line are formed; a second substrate being opposed to the first substrate, on which second substrate a common electrode is formed; and a liquid crystal material provided between the first substrate and the second substrate, the liquid crystal panel comprising:

a backup wiring for recovering a defect in the signal line; a protection circuit for electrically connecting the backup wiring to the common electrode when a potential of the backup wiring exceeds a threshold value; and

wherein the backup wiring is electrically connected to both the common electrode and a retention capacitor wiring through at least the protection circuit.

17. A liquid crystal panel including: a first substrate on which a switching element, a pixel electrode, and a signal line are formed; a second substrate being opposed to the first substrate, on which second substrate a common electrode is formed; and a liquid crystal material provided between the first substrate and the second substrate, the liquid crystal panel further comprising:

a backup wiring for recovering a defect in the signal line; a protection circuit for electrically connecting the backup wiring to the common electrode when a potential of the backup wiring exceeds a threshold value;

a plurality of retention capacitor wirings formed on the first substrate;

a major retention capacitor wiring being connected with the plurality of retention capacitor wirings,

the protection circuit electrically connecting the backup wiring also to the major retention capacitor wiring when the potential of the backup wiring exceeds the threshold value.

摘要(译)

液晶面板 (10) 包括有源矩阵基板, 在该有源矩阵基板上, 用于恢复信号线中的缺陷的晶体管 (12), 像素电极 (17), 信号线 (15,16) 和备用布线 (8a, 8b) 形成; 滤色器基板, 在其上形成公共电极 (对电极); 液晶材料设置在有源矩阵基板和滤色器基板之间。备用布线 (8a, 8b) (电连接) 到滤色器基板上的公共电极, 通过 (i) 保护电路 (9), 用于释放在备用布线 (8a, 8b) 中发生的不需要的电荷 (ii) 密封粘合剂 (6)。利用这种配置, 可以减少由备用布线中发生的不希望的电荷引起的问题 (例如, 备用布线和信号线的意外短路)。
