A liquid crystal display panel includes a first substrate, a second substrate, a liquid crystal layer and an electrode structure. The second substrate is substantially parallel to the first substrate. The liquid crystal layer is located between the first substrate and the second substrate. The electrode structure is disposed on the first substrate. The electrode structure includes a first branch portion and a second branch portion. The first branch portion includes first branch electrodes. The two adjacent first branch electrodes are substantially parallel to each other and separated apart by a first interval. The second branch portion includes second branch electrodes. The two adjacent second branch electrodes are substantially parallel to each other and separated apart by a second interval. Any first branch electrode corresponds to at least part of one of the second intervals. Any second branch electrode corresponds to at least part of one of the first intervals.

FIG. 6

LIQUID CRYSTAL DISPLAY PANEL AND LIQUID CRYSTAL DISPLAY DEVICE USING THE SAME

[0001] This application claims the benefit of Taiwan application Serial No. 98145117, filed Dec. 25, 2009, the subject matter of which is incorporated herein by reference.

BACKGROUND OF THE INVENTION

[0002] 1. Field of the Invention

[0003] The invention relates in general to a liquid crystal display panel and a liquid crystal display device using the same, and more particularly to a multi-domain liquid crystal display panel and a liquid crystal display device using the same.

[0004] 2. Description of the Related Art

[0005] In recent years, display technology has gained significant progress, and the market demand for liquid crystal display is booming. The display quality of a liquid crystal display is essential in the display industry. Currently, wide angle technology has gradually become an important factor in the quality assessment of the liquid crystal display. In the wide angle technology, multi-domain vertical alignment (MVA) technology attracts more and more interest.

[0006] In general, the liquid crystal display includes two polarizers, a liquid crystal display panel and a backlight module. The backlight module is used for providing a light source to the liquid crystal display panel, and the liquid crystal display panel is disposed between the two polarizers. The liquid crystal display panel includes two substrates and a liquid crystal layer which is disposed between the two substrates. Several pixel electrodes are disposed on one of the substrates. To provide multi domains, the pixel electrodes are patterned and divided into regions. Here, the pixel electrode includes two symmetric sub-electrode structures, for example. Each sub-electrode structure includes a stem electrode and several branch electrodes. The branch electrodes are symmetrically connected to the stem electrode.

[0007] Referring to FIG. 1, a partial diagram of the liquid crystal pointing arrows corresponding to the liquid crystal layer of a pixel electrode is shown. When a voltage is applied to the pixel electrode, the electrical field changes the directions of the liquid crystal pointing arrows, as indicated in the region A1 at the junction between two sub-electrode structures in FIG. 1. When the directions of the liquid crystal pointing arrows in the region A1 are chaotic to form nodes, streaks will occur to the display frame of the liquid crystal display panel. Therefore, the brightness of the liquid crystal display panel will be decreased during display. Or, the brightness of the liquid crystal display panel may become inconsistent during the display of frames so as to deteriorate the display quality. Besides, the generation of streaks normally increases the time for the liquid crystal display panel to resume the stable state. As a result, how to provide a liquid crystal display with excellent display quality has become an imminent task for the industries.

SUMMARY OF THE INVENTION

[0008] The invention is directed to a liquid crystal display panel and a liquid crystal display device using the same, which reduce the occurrence of streaks, increase the bright-

ness and shorten the time for resuming the stable state so as to improve the display quality and product competitiveness.

[0009] According to a first aspect of the present invention, a liquid crystal display panel including a first substrate, a second substrate, a liquid crystal layer and an electrode structure is provided. The second substrate is substantially parallel to the first substrate. The liquid crystal layer is located between the first substrate and the second substrate. The electrode structure is disposed on the first substrate. The electrode structure includes a first branch portion and a second branch portion. The first branch portion includes several first branch electrodes. The two adjacent first branch electrodes are substantially parallel to each other and separated apart by a first interval. The second branch portion includes several second branch electrodes. The two adjacent second branch electrodes are substantially parallel to each other and separated apart by a second interval. Any of the first branch electrodes corresponds to at least part of one of the second intervals. Any of the second branch electrodes corresponds to at least part of one of the first intervals.

[0010] According to a second aspect of the present invention, a liquid crystal display device including a liquid crystal display panel and a backlight module is provided. The backlight module is used for providing light to the liquid crystal display panel to display an image. The liquid crystal display panel includes a first substrate, a second substrate, a liquid crystal layer and an electrode structure. The second substrate is substantially parallel to the first substrate. The liquid crystal layer is located between the first substrate and the second substrate. The electrode structure is disposed on the first substrate. The electrode structure includes a first branch portion and a second branch portion. The first branch portion includes several first branch electrodes. The two adjacent first branch electrodes are substantially parallel to each other and separated apart by a first interval. The second branch portion includes several second branch electrodes. The two adjacent second branch electrodes are substantially parallel to each other and separated apart by a second interval. Any of the first branch electrodes corresponds to at least part of one of the second intervals, and any of the second branch electrodes corresponds to at least part of one of the first intervals.

[0011] The above and other aspects of the invention will become better understood with regard to the following detailed description of the preferred but non-limiting embodiment(s). The following description is made with reference to the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

[0012] FIG. 1 shows a partial diagram of the liquid crystal pointing arrows corresponding to the liquid crystal layer of a pixel electrode;

[0013] FIG. 2A shows a liquid crystal display device according to a first embodiment of the invention;

[0014] FIG. 2B shows an electrode structure in FIG. 2A;

[0015] FIG. 2C shows liquid crystal pointing arrows of the liquid crystal layer in FIG. 2A corresponding to a region in FIG. 2B;

[0016] FIG. 3 shows an electrode structure according to a second embodiment of the invention;

[0017] FIG. 4 shows an electrode structure according to a third embodiment of the invention;

[0018] FIG. 5 shows an electrode structure according to a fourth embodiment of the invention; and

[0019] FIG. 6 shows an electrode structure according to a fifth embodiment of the invention.

DETAILED DESCRIPTION OF THE INVENTION

[0020] The liquid crystal display panel and the liquid crystal display device using the same disclosed in the invention are elaboration in a number of embodiments below with accompanying drawings. However, anyone who is skilled in the art of the invention will understand that these drawings and disclosures are for elaboration purpose only, not for limiting the scope of protection of the invention.

First Embodiment

[0021] Referring to FIG. 2A, a liquid crystal display device according to a first embodiment of the invention is shown. The liquid crystal display device includes a liquid crystal display panel 100, a backlight module 200 and polarizers 310 and 320. The absorption axes of the polarizers 310 and 320 are perpendicular to each other. The liquid crystal display panel 100 is disposed between the polarizers 310 and 320. The backlight module 200 is used for providing light for the liquid crystal display panel 100 to display an image.

[0022] The liquid crystal display panel 100 includes a first substrate 110, a second substrate 120, an electrode structure 130 and a liquid crystal layer 140. The second substrate 120 is substantially parallel to the first substrate 110. The liquid crystal layer 140 is located between the first substrate 110 and the second substrate 120. The electrode structure 130 is disposed on the first substrate 110.

[0023] Referring to FIG. 2B, an electrode structure 130 in FIG. 2A is shown. The electrode structure 130 includes a first stem electrode 131*t*, a first branch portion 131*b*, a second stem electrode 132*t* and a second branch portion 132*b*. Let the first stem electrode 131*t* and the first branch portion 131*b* be viewed as a sub-electrode structure S11, and the second stem electrode 132*t* and the second branch portion 132*b* be viewed as a sub-electrode structure S12, the sub-electrode structures S11 and S12 are horizontally adjacent to each other and can respectively be viewed as a first bright region and a second bright region. When an image is displayed, the first bright region and the second bright region can be mixed and displayed in a pixel to produce low color shift effect. Thus, the display quality of the liquid crystal display panel 100 is even more dedicated.

[0024] The first stem electrode 131*t* is, for example, cross-shaped, and the first branch portion 131*b* includes several first branch electrodes 131*b*1. The first branch electrodes 131*b*1 are connected to the first stem electrode 131*t*. The two adjacent first branch electrodes 131*b*1 are substantially parallel to each other and separated apart by a first interval d11. Besides, the second stem electrode 132*t* is, for example, cross-shaped, and the second branch portion 132*b* includes several second branch electrodes 132*b*1. The second branch electrodes 132*b*1 are connected to the second stem electrode 132*t*. The two adjacent second branch electrodes 132*b*1 are substantially parallel to each other and separated apart by a second interval d12. Any of the first branch electrodes 131*b*1 corresponds to at least part of one of the second intervals d12, and any of the second branch electrodes 132*b*1 corresponds to at least part of one of the first intervals d11.

[0025] In the present embodiment of the invention, the end edge E11 of each first branch electrode 131*b*1 is located on a first dummy line L11, and the end edge E12 of each second

branch electrode 132*b*1 is located on a second dummy line L12. The first dummy line L11 is substantially parallel to the second dummy line L12. Let the length of one first interval d11 and one first branch electrode 131*b*1 being on the first dummy line L11 be a unit length U1, and the length of one second interval d12 and one second branch electrodes 132*b*1 being on the second dummy line L12 be the unit length U1, the first dummy line L11 and the second dummy line L12 are, for example, separated apart by a half of the unit length U1. That is, if the unit length U1 is 10 μ m, the first dummy line L11 and the second dummy line L12 are separated apart by 5 μ m. Thus, the end edge E11 of any of the first branch electrodes 131*b*1 exactly corresponds to one of the second intervals d12, and the end edge E12 of any of the second branch electrodes 132*b*1 exactly corresponds to one of the first intervals d11.

[0026] Referring to FIG. 2C, liquid crystal pointing arrows of the liquid crystal layer 140 in FIG. 2A corresponding to a region A21 in FIG. 2B are shown. When pixels are switched between the bright state and the dark state, the fringe field at the junction between the first branch portion 131*b* and the second branch portion 132*b* guides the liquid crystal molecules to tilt to a consistent direction, as indicated in the region A22. Thus, fewer nodes are generated at the junction between the first branch portion 131*b* and the second branch portion 132*b*, so that the liquid crystal display panel 100 has fewer occurrences of streaks and brightness drop. According to the simulation results, if the liquid crystal molecules are distributed as indicated by the liquid crystal pointing arrows in FIG. 1, then the liquid crystal molecules spend about 130 ms to resume the stable state. For the liquid crystal display panel 100 of the present embodiment of the invention, the occurrence of streaks is reduced, and the time for resuming the stable state after the occurrence of streaks is effectively reduced to 20 ms.

[0027] In the present embodiment of the invention, the sub-electrode structure S11 and S12 is, for example, disposed in a pixel. However, anyone who is skilled in the technology of the invention will understand that the sub-electrode structure S11 and S12 can also be disposed in two adjacent pixels so as to reduce the occurrence of streaks, increase brightness and shorten the time for resuming the stable state.

Second Embodiment

[0028] Referring to FIG. 3, an electrode structure 230 according to a second embodiment of the invention is shown. A first branch portion 231*b* of an electrode structure 230 includes several first branch electrodes 231*b*1. The two adjacent first branch electrodes 231*b*1 are substantially parallel to each other and separated apart by a first interval d21. A second branch portion 232*b* of the electrode structure 230 includes several second branch electrodes 232*b*1. The two adjacent second branch electrodes 232*b*1 are substantially parallel to each other and separated apart by a second interval d22. In the present embodiment of the invention, any of the second branch electrodes 232*b*1 corresponds to at least part of one of the first intervals d21, and any of the first branch electrodes 231*b*1 corresponds to at least part of one of the second intervals d22, so the advantages of the liquid crystal display panel equipped with the electrode structure 230 are similar to that of the liquid crystal display panel 100 of the first embodiment.

[0029] In the present embodiment of the invention, one end of each first branch electrode 231*b*1 is connected to the first stem electrode 231*t*, and the other end of each first branch

electrode **231b1** has two corners formed by an end edge **E21** and two sides **Si21**. The two corners are, for example, 90°. Furthermore, one end of each second branch electrode **232b1** is connected to the second stem electrode **232t**, and the other end of each second branch electrode **232b1** has two corners formed by an end edge **E22** and two sides **Si22**. The two corners are, for example, 90°.

[0030] Thus, the end edge **E21** of any of the first branch electrodes **231b1** corresponds to the side **Si22** of one of the second branch electrodes **232b1**, and the end edge **E22** of any of the second branch electrodes **232b1** corresponds to the side **Si21** of one of the first branch electrodes **231b1**. Let the length of one first interval **d21** and a part of one first branch electrode **231b1** being on a first dummy line **L21** be a unit length **U2**, and the length of one second interval **d22** and a part of one second branch electrode **232b1** being on a second dummy line **L22** be the unit length **U2**, the end edge **E21** of the first branch electrode **231b1** and the side **Si22** of the adjacent second branch electrode **232b1** are separated apart by a half of the unit length **U2**, and the end edge **E22** of the second branch electrode **232b1** and the side **Si21** of the adjacent first branch electrode **231b1** are separated apart by a half of the unit length **U2**, for example. That is, if the unit length **U2** is 10 μm , then the end edge **E21** of the first branch electrode **231b1** and the side **Si22** of the adjacent second branch electrode **232b1** are separated apart by 5 μm , and the end edge **E22** of the second branch electrode **232b1** and the side **Si21** of the adjacent first branch electrode **231b1** are separated apart by 5 μm . Let the unit length **U2** of the present embodiment of the invention be equal to the unit length **U1** of the first embodiment. The interval **de** between a line **Le1** formed by several corners of the first branch electrodes **231b1** and a line **Le2** formed by several corners of the second branch electrodes **232b1** is smaller than the interval between the first branch electrode **131b1** and the second branch electrode **132b1** of the first embodiment. In other words, as the corners of each first branch electrode **231b1** and the corners of each second branch electrode **232b1** protrude inwardly, the interval **de** is reduced, so that the width of the corresponding streak is reduced and the display quality is increased.

Third Embodiment

[0031] Referring to FIG. 4, an electrode structure **330** according to a third embodiment of the invention is shown. The electrode structure **330** includes a sub-electrode structure **S31** including a first stem electrode **331t** and a first branch portion **331b**, and a sub-electrode structure **S32** including a second stem electrode **332t** and a second branch portion **332b**. The sub-electrode structures **S31** and **S32** are vertically adjacent to each other.

[0032] Since any of second branch electrodes **332b1** of the second branch portion **332b** corresponds to at least part of one first interval **d31**, and any of first branch electrodes **331b1** of the first branch portion **331b** corresponds to at least part of one second interval **d32**, the liquid crystal display panel equipped with the electrode structure **330** has similar advantages like the liquid crystal display panel **100** of the first embodiment.

Fourth Embodiment

[0033] Referring to FIG. 5, an electrode structure **430** according to a fourth embodiment of the invention is shown. The electrode structure **430** includes a stem electrode **430t**, a

first branch portion **431b** and a second branch portion **432b**. The stem electrode **430t** is, for example, cross-shaped, and the first branch portion **431b** and the second branch portion **432b** are respectively connected to two opposite sides of the stem electrode **430t**.

[0034] Since any of second branch electrodes **432b1** of the second branch portion **432b** corresponds to at least part of one first interval **d41**, and any of first branch electrodes **431b1** of the first branch portion **431b** corresponds to at least part of one second interval **d42**, the liquid crystal display panel equipped with the electrode structure **430** has similar advantages like the liquid crystal display panel **100** of the first embodiment.

Fifth Embodiment

[0035] Referring to FIG. 6, an electrode structure **530** according to a fifth embodiment of the invention is shown. The electrode structure **530** includes a main electrode **530m**, a first branch portion **531b** and a second branch portion **532b**. The main electrode **530m** has a first inclined side **R1** and a second inclined side **R2**. The first inclined side **R1** and the second inclined side **R2** form an indent. Each first branch electrode **531b1** of the first branch portion **531b** is connected to the first inclined side **R1** to be located inside the indent. Each second branch electrode **532b1** of the second branch portion **532b** is connected to the second inclined side **R2** to be located inside the indent.

[0036] Since any of the second branch electrodes **532b1** corresponds to at least part of one of the first intervals **d51**, and any of the first branch electrodes **531b1** corresponds to at least part of one of the second intervals **d52**, the liquid crystal display panel equipped with the electrode structure **530** has similar advantages like the liquid crystal display panel **100** of the first embodiment.

[0037] According to the liquid crystal display panel and the liquid crystal display device using the same disclosed in the above embodiments of the invention, through the disposition of the first branch portion and the second branch portion adjacent to each other, the occurrence of nodes at the junction between the first branch portion and the second branch portion can be reduced so as to increase the overall display brightness. Moreover, since the time for resuming the stable state after the occurrence of streaks is shortened, the display quality can be further improved.

[0038] While the invention has been described by way of example and in terms of the preferred embodiment(s), it is to be understood that the invention is not limited thereto. On the contrary, it is intended to cover various modifications and similar arrangements and procedures, and the scope of the appended claims therefore should be accorded the broadest interpretation so as to encompass all such modifications and similar arrangements and procedures.

What is claimed is:

1. A liquid crystal display panel, comprising:
 - a first substrate;
 - a second substrate substantially parallel to the first substrate;
 - a liquid crystal layer located between the first substrate and the second substrate; and
 - an electrode structure disposed on the first substrate, wherein the electrode structure comprises:
 - a first branch portion comprising a plurality of first branch electrodes, wherein the two adjacent first

- branch electrodes are substantially parallel to each other and separated apart by a first interval; and
 a second branch portion comprising a plurality of second branch electrodes, wherein the two adjacent second branch electrodes are substantially parallel to each other and separated apart by a second interval, any of the first branch electrodes corresponds to at least part of one of the second intervals, and any of the second branch electrodes corresponds to at least part of one of the first intervals.
2. The liquid crystal display panel according to claim 1, wherein the electrode structure further comprises:
 - a first stem electrode, wherein the first branch electrodes are connected to the first stem electrode; and
 - a second stem electrode, wherein the second branch electrodes are connected to the second stem electrode.
 3. The liquid crystal display panel according to claim 2, wherein the first stem electrode is cross-shaped, and the second stem electrode is cross-shaped.
 4. The liquid crystal display panel according to claim 1, wherein the electrode structure further comprises:
 - a stem electrode, wherein the first branch portion and the second branch portion are connected to two opposite sides of the stem electrode, respectively.
 5. The liquid crystal display panel according to claim 4, wherein the stem electrode is cross-shaped.
 6. The liquid crystal display panel according to claim 1, wherein the electrode structure further comprises:
 - a main electrode having a first inclined side and a second inclined side, wherein the first inclined side and the second inclined side form an indent, each first branch electrode is connected to the first inclined side to be located inside the indent, and each second branch electrode is connected to the second inclined side to be located inside the indent.
 7. The liquid crystal display panel according to claim 1, wherein the end edge of each first branch electrode is located on a first dummy line, the end edge of each second branch electrode is located on a second dummy line, and the first dummy line is substantially parallel to the second dummy line.
 8. The liquid crystal display panel according to claim 7, wherein the length of one of the first intervals and one of the first branch electrodes being on the first dummy line is a unit length, the length of one of the second intervals and one of the second branch electrodes being on the second dummy line is the unit length, and the first dummy line and the second dummy line are separated apart by a half of the unit length.
 9. The liquid crystal display panel according to claim 1, wherein two corners of each first branch electrode are both 90°, and two corners of the second branch electrode are both 90°.
 10. The liquid crystal display panel according to claim 9, wherein the length of a part of one of the first branch electrodes and one of the first intervals being on a first dummy line is a unit length, the length of a part of one of the second branch electrodes and one of the second intervals being on a second dummy line is the unit length, the end edge of one of the first branch electrodes and the side of the adjacent second branch electrode are separated apart by a half of the unit length, and the end edge of one of the second branch electrodes and the side of the adjacent first branch electrode are separated apart by a half of the unit length.
 11. A liquid crystal display device, comprising:
 - a liquid crystal display panel, comprising:
 - a first substrate;
 - a second substrate substantially parallel to the first substrate;
 - a liquid crystal layer located between the first substrate and the second substrate; and
 - an electrode structure disposed on the first substrate, the electrode structure comprises:
 - a first branch portion comprising a plurality of first branch electrodes, wherein the two adjacent first branch electrodes are substantially parallel to each other and separated apart by a first interval; and
 - a second branch portion comprising a plurality of second branch electrodes, wherein the two adjacent second branch electrodes are substantially parallel to each other and separated apart by a second interval, any of the first branch electrodes corresponds to at least part of one of the second intervals, and any of the second branch electrodes corresponds to at least part of one of the first intervals; and
 - a backlight module used for providing light to the liquid crystal display panel to display an image.
 12. The liquid crystal display device according to claim 11, wherein the electrode structure further comprises:
 - a first stem electrode, wherein the first branch electrodes are connected to the first stem electrode; and
 - a second stem electrode, wherein the second branch electrodes are connected to the second stem electrode.
 13. The liquid crystal display device according to claim 12, wherein the first stem electrode is cross-shaped, and the second stem electrode is cross-shaped.
 14. The liquid crystal display device according to claim 11, wherein the electrode structure further comprises:
 - a stem electrode, wherein the first branch portion and the second branch portion are connected to two opposite sides of the stem electrode, respectively.
 15. The liquid crystal display device according to claim 14, wherein the stem electrode is cross-shaped.
 16. The liquid crystal display device according to claim 11, wherein the electrode structure further comprises:
 - a main electrode having a first inclined side and a second inclined side, wherein the first inclined side and the second inclined side form an indent, each first branch electrode is connected to the first inclined side to be located inside the indent, and each second branch electrode is connected to the second inclined side to be located inside the indent.
 17. The liquid crystal display device according to claim 11, wherein the end edge of each first branch electrode is located on a first dummy line, the end edge of each second branch electrode is located on a second dummy line, and the first dummy line is substantially parallel to the second dummy line.
 18. The liquid crystal display device according to claim 17, wherein the length of one of the first intervals and one of the first branch electrodes being on the first dummy line is a unit length, the length of one of the second intervals and one of the second branch electrodes being on the second dummy line is the unit length, and the first dummy line and the second dummy line are separated apart by a half of the unit length.
 19. The liquid crystal display device according to claim 11, wherein the two corners of each first branch electrode are both 90°, and two corners of the second branch electrode are both 90°.

20. The liquid crystal display device according to claim **19**, wherein the length of a part of one of the first branch electrodes and one of the first intervals being on a first dummy line is a unit length, the length of a part of one of the second branch electrode and one of the second intervals being on a second dummy line is the unit length, the end edge of one of the first

branch electrodes and the side of the adjacent second branch electrode are separated apart by a half of the unit length, and the end edge of one of the second branch electrodes and the side of the adjacent first branch electrode are separated apart by a half of the unit length.
