Description

[0001] This application claims priority to and the benefit of Korean Application No. 2002-0015437, filed on March 21, 2002 in the Korean Intellectual Property Office, the entire disclosure of which is incorporated herein by reference.

BACKGROUND OF THE INVENTION**(a) Field of the Invention**

[0002] The present invention relates to a display and a driving method thereof, and more particularly to an organic electroluminescence (hereinafter, "EL") display of an active matrix driving method.

(b) Description of the Related Art

[0003] In general, an organic EL display is a display that emits light by electrical excitation of fluorescent organic compound and displays image by driving each of M N organic luminescent cells with voltage or current.

[0004] This organic cell has a structure of an anode (ITO), an organic thin film and, a cathode layer (metal). The organic thin film is formed as a multi-layered structure including an emission layer ("EML"), an electron transport layer ("ETL"), and a hole transport layer ("HTL") so as to increase luminescence efficiency by balancing electron and hole concentrations. In addition, it can include an electron injection layer ("EIL") and a hole injection layer ("HIL") separately.

[0005] Organic EL displays that use organic luminescent cells like the above are configured as passive matrix or active matrix that includes thin film transistors (TFTs). In the passive matrix configuration, organic luminescent cells are formed between anodes and cathodes lines that cross each other and driven by driving those lines. While in the active matrix configuration, each organic luminescent cell is connected to a TFT usually through an ITO electrode and driven by controlling the gate voltage of the corresponding TFT.

[0006] Fig. 1 is a circuit diagram of a conventional pixel for driving the organic EL display using TFTs, and it is a representative of M N pixels. Referring to Fig. 1, driving transistor Mb is connected to organic EL device OLED to supply current for emitting light. The amount of current through driving transistor Mb is controlled by data voltage applied through switching transistor Ma. In this case, capacitor C1 for maintaining the applied voltage during a certain period is connected between source and gate of transistor Mb. Scan line X_M is connected to the gate of transistor Ma, and data line Y_N is connected to the source thereof.

[0007] Operation of the pixel is as follows. When switching transistor Ma is turned on by the selection signal applied to the gate thereof, a data voltage is applied to node A, the gate of the driving transistor through the data line. Then, a current corresponding to the data voltage applied to the gate thereof flows into the organic EL device OLED to emit light.

[0008] In this case, current I_{OLED} flowing through organic EL device OLED is referred to as Equation 1.

$$I_{OLED} = \frac{\beta}{2} (V_{GS} - V_{TH})^2 = \frac{\beta}{2} (V_{DD} - V_{DATA} - |V_{TH}|)^2 \quad (1)$$

wherein, I_{OLED} is a current flowing through organic EL device OLED, V_{GS} is the gate-to-source voltage of transistor Mb, V_{TH} is a threshold voltage of transistor Mb, V_{DATA} is a data voltage and β is a constant.

[0009] As expressed in Equation 1, according to the pixel circuit of Fig. 1, the current corresponding to the applied data voltage is supplied to organic EL device OLED, and organic EL device OLED emits light in correspondence to the supplied current. Herein, the applied data voltage has many levels to express corresponding gray levels.

[0010] However, in the conventional pixel as described above, there is a problem in that high gray scale is difficult to obtain due to variation of the threshold voltage of TFTs generated by manufacture process. For example, when driving transistor Mb is supplied with data voltage in the range of 3 volts, two data voltages representing adjacent gray levels must be apart from each other by approximately 12mV ($=3V/256$) so as to implement 8-bit (256) gray scale. If the threshold voltage varies in 100mV range, which is usually the case, it is difficult to discriminate one data voltage from another and, as a result, gray scale is reduced.

[0011] Document EP 1 220 191 discloses an OLED display device comprising several pixel circuits each of which having a switch for switching the voltage applied to a data line in response to a select signal supplied to a scan line. A thin film transistor supplies current to an organic EL element in response to the voltage applied to the TFT gate through the switch and a capacitor maintains the applied voltage. The threshold voltage deviation of the driving TFT is compensated by coupling its gate to another gate of another TFT thereby creating a first precharge process.

[0012] The document US 5 510 807 discloses an LCD data driver circuit integrated onto a display substrate, a de-

multiplexer circuit demultiplexes a group of Y columns of multiplexed video data signals to X groups of Y pixel capacitors precharged before video signal applied, thereby creating only a part of a second precharge process.

SUMMARY OF THE INVENTION

[0013] In accordance with the present invention as defined in the set of claims 1 to 26 precharge voltages are applied to data lines to display high gray scale by compensating for variation of threshold voltage and to remove poor images due to operating characteristics of thin film transistors of pixel circuits. According to first to third aspects of the present invention, an organic EL display is provided, which includes: a plurality of data lines transmitting data voltages; a plurality of scan lines transmitting selection signals; a plurality of pixel circuits; and a data driver. The pixel circuits are provided in pixel areas defined by two adjacent data lines and two adjacent scan lines and include first and second switching elements, first thin film transistors, and capacitors. The first switching elements respond to the selection signals applied to the scan lines to transmit the data voltages applied to the data lines, and the first thin film transistors supply currents to organic electroluminescence devices in correspondence to the data voltages inputted to gates thereof through the first switching elements. The capacitors maintain the data voltages during a certain period, and the second switching elements apply first precharge voltage to the capacitors in response to control signals while the selection signals are applied to previous scan lines.

[0014] In this case, it is preferable that the control signals are separate reset signals or selection signals applied to previous scan lines.

[0015] According to the first aspect of the present invention, the data driver divides a plurality of data lines into a plurality of groups to apply data voltage corresponding to the respective groups, and the organic EL display preferably further includes a demultiplexer. The demultiplexer applies data voltages sequentially applied from the data driver to the corresponding data lines and applies second precharge voltages to data lines of at least one group before selection signals for selecting scan lines are applied to the scan lines connected to the pixel circuits.

[0016] According to the second aspect, the data driver applies the data voltages to respective data lines sequentially, and the organic EL display preferably further includes a precharge means, which applies second precharge voltages to the data lines simultaneously before selection signals for selecting scan lines are applied to the scan lines connected to the pixel circuits.

[0017] According to the third aspect, the data driver applies the data voltages to respective data lines, and the organic EL display preferably further includes a precharge means. The precharge means simultaneously applies second precharge voltages to all data lines before selection signals for selecting scan lines are applied to the scan lines connected to the pixel circuits and sequentially stops the application of the second precharge voltages before the data voltages are applied to the respective data lines sequentially.

[0018] In the organic EL display according to the first to the third aspects of the present invention, the pixel circuits may further include second thin film transistors of which the gates are connected to the gates of the first thin film transistors and that are diode-connected between the first and the second switching elements. In this case, the second precharge voltage preferably has a value equal to the first precharge voltage or a value further from the data voltage than that. In addition, the second precharge voltage preferably has a constant value.

[0019] According to the fourth aspect, a method of driving such an organic EL display is provided. First, the capacitor of the pixel circuit connected to i-th scan line is precharged with the first precharge voltage while selection signal is applied to (i-1)th scan line. And, the data lines are applied with second precharge voltages before selection signal is applied to the i-th scan line. Next, data voltages are sequentially applied to corresponding groups of data lines which consist of at least one data line and applications of the second precharge voltages to each group of data lines are stopped before the data voltages are applied to those lines.

[0020] According to a fifth aspect, a display is provided, which includes a plurality of data lines, a plurality of scan lines, a plurality of pixel circuits, a data driver, and a scan driver. The pixel circuits are provided in pixel areas defined by two adjacent data lines and two adjacent scan lines. Each of the pixel circuits includes a first switching element responding to selection signal applied to the scan line to transmit data voltage applied to the data line, a capacitor for maintaining the data voltage during a certain period, and a second switching element applying a first precharge voltage to the capacitor in response to control signal while selection signal is applied to the previous scan line.

[0021] In this case, the data driver divides a plurality of data lines into a plurality of groups each of which consists of at least one data line and applies corresponding data voltages to the respective groups sequentially. Second precharge voltages are applied to data lines of at least one group before selection signals for selecting scan lines are applied to the scan lines connected to the pixel circuits, and the application of second precharge voltages is stopped when corresponding data voltages are applied to the respective groups.

[0022] Control signals are preferably selection signals applied to previous scan lines or separate reset signals.

BRIEF DESCRIPTION OF THE DRAWINGS**[0023]**

Fig. 1 shows a circuit diagram of a pixel of an organic EL display according to the prior art.
 Fig. 2 and Fig. 4 show organic EL displays according to first and second embodiments of the present invention, respectively.
 Fig. 3A and Fig. 3B show a representative pixel of the first embodiment and a modified example thereof according to the present invention, respectively.
 Fig. 5 shows a demultiplexer of the organic EL display according to the second embodiment of the present invention.
 Fig. 6 shows a timing diagram of the organic EL display according to the second embodiment of the present invention.
 Fig. 7 and Fig. 9 show organic EL displays according to a third and a fourth embodiments of the present invention, respectively.
 Fig. 8 and Fig. 10 show timing diagrams of the organic EL displays according to the third and the fourth embodiments of the present invention.
 Fig. 11 shows a timing diagram of an organic EL display according to a fifth and a sixth embodiments of the present invention.
 Fig. 12 shows a precharge control signal generator in the organic EL display according to the fifth embodiment of the present invention.
 Fig. 13 shows an output part of a shift register in the organic EL display according to the sixth embodiment of the present invention.

DETAILED DESCRIPTION

[0024] In the description set forth herein similar parts are denoted by the same reference numerals. When a part is connected to another part, the part is not only directly connected to another part but also electrically connected (coupled) to another part with another device intervening in them.

[0025] First, referring to Fig. 2, Fig. 3A, and Fig. 3B, an organic EL display and a driving method thereof according to a first embodiment of the present invention will be described.

[0026] Fig. 2 shows an organic EL display according to a first embodiment of the present invention, and Fig. 3A and Fig. 3B show a representative pixel of the first embodiment and a modified example thereof according to the present invention, respectively.

[0027] As shown in Fig. 2, the organic EL display according to the first embodiment of the present invention includes organic EL display panel 110, scan driver 120, and data driver 130.

[0028] Organic EL display panel 110 includes a plurality of data lines Y_1 to Y_N transmitting data voltages, a plurality of scan lines X_1 to X_M transmitting selection signals, and a plurality of pixel circuits 112. Pixel circuits 112 are provided in pixel areas defined by two adjacent data lines and two adjacent scan lines. Scan driver 120 applies the selection signals to scan lines X_1 to X_M , and data driver 130 applies the data voltages representing image signals to data lines Y_1 to Y_N .

[0029] As shown in Fig. 3A, pixel circuit 112 according to the first embodiment of the present invention includes organic EL device OLED; transistors M1, M2, M3, and M4; and capacitor C1.

[0030] Transistor M3 has a gate connected to scan line X_m , a source connected to the data line and a drain connected to a source of transistor M2, to transmit the data voltage to transistor M2 in response to the selection signal applied to scan line X_m .

[0031] The gate and the drain of transistor M2 are connected with each other so as to work as a diode (diode-connected) to transmit the data voltage from transistor M3 to transistor M1.

[0032] Transistor M1 has a source connected to power voltage VDD, a drain connected to organic EL device OLED, and a gate connected to the drain of transistor M2, and supplies a current corresponding to the data voltage from transistor M2 to organic EL device OLED. Organic EL device OLED emits light corresponding to the supplied current.

[0033] Capacitor C1 is connected between power voltage VDD and the gate of transistor M1 to maintain the data voltage and precharge voltage V_p applied to the gate of transistor M1 during a specific period.

[0034] Transistor M4 has a gate connected to previous scan line X_{m-1} , a source connected to the drain of transistor M2, and a drain connected to the precharge voltage V_p is applied to, and initializes the gate of transistor M1 to precharge voltage V_p in response to the selection signal applied to previous scan line X_{m-1} .

[0035] In this case, precharge voltage V_p is preferably set to a somewhat smaller value than that of a voltage of node A corresponding to the highest gray level (i.e., a voltage corresponding to the minimum voltage applied to the data line).

[0036] Once transistor M3 is turned on by the selection signal applied to scan line X_m , the data voltage applied to the data line is transmitted to the gate (node A) of driving transistor M1 through transistor M2. Then, a current corresponding

to the data voltage applied to the gate thereof flows through organic EL device OLED, passing through transistor M1, to emit light.

[0037] In this case, the current flowing through organic EL device OLED according to the first embodiment of the present invention is as following Equation 2.

$$I_{OLED} = \frac{\beta}{2} (V_{GS} - V_{TH1})^2 = \frac{\beta}{2} (V_{DD} - (V_{DATA} - |V_{TH2}|) - V_{TH1})^2 \quad (2)$$

[0038] Wherein, I_{OLED} is a current flowing through organic EL device OLED, V_{GS} is a gate-to-source voltage of transistor M1, V_{TH1} is a threshold voltage of transistor M1, V_{TH2} is a threshold voltage of transistor M2, and β is a constant.

[0039] In this case, if the threshold voltages of transistor M1 and transistor M2 are equal, i.e., $V_{TH1} = V_{TH2}$, Equation 2 can be expressed as the following Equation 3. In practice, according to the first embodiment, since the two transistors M1 and M2 are adjacent to each other to be influenced almost equally by the process, difference between the threshold voltages of the two transistors M1 and M2 is negligible, and thereby the threshold voltages become equal.

$$I_{OLED} = \frac{\beta}{2} (V_{DD} - V_{DATA})^2 \quad (3)$$

[0040] Therefore, according to the first embodiment of the present invention, as seen in Equation 3, current I_{OLED} corresponding to the data voltage applied to the data line flows in organic EL device OLED regardless of the threshold voltage of current driving transistor M1. That is, since transistor M2 compensates for the variation of the threshold voltage of current driving transistor M1, the current flowing through organic EL device OLED can be controlled minutely to provide an organic EL display of high gray scale.

[0041] Although transistors M1, M2, M3, and M4 of pixel circuit 112 have been described with PMOS transistors in the first embodiment of the present invention, the present invention is not limited to this but may use NMOS transistors or the combination of PMOS and NMOS transistors. Since modification of pixel circuits for these cases can be easily configured by those who have common knowledge in the fields related to this invention, no detailed description will be included herein.

[0042] In addition, in the first embodiment of the present invention, transistor M4 is driven by the selection signal of previous scan line X_{m-1} in order to initialize the gate of transistor M1 of pixel circuit 112 to precharge voltage V_p . However, as shown in Fig. 3B, transistor M4 may be driven by applying a separate reset signal to the gate of transistor M4 without applying the selection signal of previous scan line X_{m-1} to the gate thereof.

[0043] Herein, when the data voltages are applied to the data lines, the data voltages may be applied to all data lines Y_1 to Y_N not at once, but sequentially. In the case wherein the data voltages are applied sequentially, when a data voltage is applied to data line Y_1 with scan line X_m selected, in data line Y_2 , the data voltage applied at the time of selecting previous scan line X_{m-1} is stored in a parasitic capacitor, and precharge voltage V_p is stored in capacitor C1 of pixel circuit 112.

[0044] In this case, if diode element M2 is turned on by difference between the voltage of the parasitic capacitor and the voltage of capacitor C1, the charges are redistributed between the parasitic capacitor and capacitor C1 to change the voltage of capacitor C1. As a result, transistor M2 may not be turned on by difference between the changed voltage of capacitor C1 and the data voltage applied to data line Y_2 later, and in this case, a desired voltage is not applied to capacitor C1 and desired images cannot be obtained.

[0045] To solve the above problem, precharge voltage V_{pre} is applied to the data line to which the data voltage is not applied to charge the data line with precharge voltage V_{pre} , and thereby, transistor M2 cannot be turned on by the difference between the voltage of capacitor C1 and precharge voltage V_{pre} . Herein, precharge voltage V_{pre} is equal to 'precharge voltage V_p - threshold voltage V_{TH2} ' or further from the data voltage than that, so that transistor M2 is not turned on. The threshold voltage V_{TH2} is negative in case transistor M2 is a PMOS transistor, and threshold voltage V_{TH2} is positive in case transistor M2 is an NMOS transistor.

[0046] Now, a method of driving an organic EL display by applying such a precharge voltage V_{pre} will be described.

[0047] First, referring to Fig. 4 to Fig. 6, an organic EL display and a driving method thereof according to a second embodiment of the present invention will be described.

[0048] Fig. 4 shows an organic EL display according to a second embodiment of the present invention, and Fig. 5 shows a demultiplexer of the organic EL display according to the second embodiment of the present invention. Fig. 6

shows a timing diagram of the organic EL display according to the second embodiment of the present invention.

[0049] As shown in Fig. 4, organic EL display 200 according to the second embodiment of the present invention includes organic EL display panel 210, scan driver 220, data driver 230 and demultiplexer 240.

[0050] The organic EL display according to the second embodiment of the present invention has the same configuration as that of the first embodiment except for data driver 230 and demultiplexer 240. Pixel circuit 212 of organic EL display panel 210 includes pixel circuit 112 according to the first embodiment of the present invention and all the pixel circuits capable of being modified in the first embodiment of the present invention.

[0051] Data driver 230 outputs the data voltages to demultiplexer 240 per R (red), G (green), and B (blue) sequentially under the control of a controller (not shown). When the number of data lines $Y_1, Y_2, Y_3, Y_4, Y_5, Y_6, \dots, Y_{3n-2}, Y_{3n-1}$, and Y_{3n} is $3n$, i.e., data lines $Y_1, Y_4, \dots, Y_{3n-2}$ transmitting the R data voltages, data lines $Y_2, Y_5, \dots, Y_{3n-1}$ transmitting the G data voltages, and data line $Y_3, Y_6, \dots, Y_{3n}$ transmitting the B data voltages, the number of signal lines $D_1, D_2, \dots, D_n$ transmitting the data voltages from the data driver to demultiplexer 240 is n in correspondence to each one of R, G and B data lines.

[0052] In this way, data driver 230 sequentially outputs R, G and B data voltages to signal lines $D_1, D_2, \dots, D_n$ under the control of the controller.

[0053] As shown in Fig. 5, demultiplexer 240 is supplied with the data voltages per R, G, and B from data driver 230, and then, it outputs the R, G, and B data voltages to respective data lines sequentially.

[0054] Demultiplexer 240 includes data voltage supplying switching elements $MR_1, MG_1, MB_1, MR_2, MG_2, MB_2, \dots, MR_n, MG_n$, and MB_n and precharge voltage supplying switching elements $PG_1, PB_1, PG_2, PB_2, \dots, PG_n$, and PB_n composed of PMOS transistors.

[0055] Data lines Y_1, Y_2 , and Y_3 are connected to signal line D_1 in parallel with each other through the respective switching elements MR_1, MG_1 , and MB_1 , and data lines Y_4, Y_5 , and Y_6 are connected to data line D_2 in parallel with each other through the respective switching elements MR_2, MG_2 , and MB_2 . In this way, data lines Y_{3n-2}, Y_{3n-1} , and Y_{3n} are connected to signal line D_n through the respective switching elements MR_n, MG_n , and MB_n . In addition, switching elements $PG_1, PB_1, PG_2, PB_2, \dots, PG_n$, and PB_n are connected between precharge voltage V_{pre} and data lines $Y_2, Y_3, Y_5, Y_6, \dots, Y_{3n-1}$, and Y_{3n} .

[0056] Data voltage supplying switching elements MR_1 to MR_n are connected to switching signal line 241, and transmit the R data voltages to data lines $Y_1, Y_4, \dots, Y_{3n-2}$ and pixel circuits 212 in response to switching signal H_R applied from the controller through signal lines 241. Data voltage supplying switching elements MG_1 to MG_n are connected to switching signal line 243, and apply the G data voltages to data lines $Y_2, Y_5, \dots, Y_{3n-1}$ and pixel circuits 212 in response to switching signal H_G . In addition, data voltage supplying switching elements MB_1 to MB_n are connected to switching signal line 245, and apply the B data voltages to data lines $Y_3, Y_6, \dots, Y_{3n}$ and pixel circuits 212 in response to switching signal H_B .

[0057] In addition, the precharge voltage supplying switching elements PG_1 to PG_n are connected to signal line 242 and transmit precharge voltages V_{pre} via data lines $Y_2, Y_5, \dots, Y_{3n-1}$ to pixel circuits 212 in response to switching signal P_G applied through signal line 242 from the controller. Precharge voltage supplying switching elements PB_1 to PB_n are connected to signal line 244 and transmit precharge voltages V_{pre} via data lines $Y_3, Y_6, \dots, Y_{3n}$ to pixel circuits 212 in response to switching signal P_B .

[0058] Such precharge voltages V_{pre} must have a value equal to 'precharge voltage V_p - threshold voltage V_{TH2} ' or a value that is further from the data voltages than that, compared with precharge voltage V_p applied to capacitor $C1$. In this way, transistor M2 is not turned on by the difference between voltage V_{pre} stored in the data line and voltage V_p stored in capacitor $C1$.

[0059] In the second embodiment of the present invention, although transistors M1, M2, M3, and M4 of pixel circuit 212; data voltage supplying switching elements $MR_1, MG_1, MB_1, MR_2, MG_2, MB_2, \dots, MR_n, MG_n$, and MB_n ; and precharge voltage supplying switching elements $PG_1, PB_1, PG_2, PB_2, \dots, PG_n$, and PB_n have been described using PMOS transistors, the present invention is not limited to these but may use NMOS transistors or a combination of PMOS transistors and NMOS transistors. Since alternative circuit configurations and driving signals in accordance with the teachings of the present invention will be apparent those skilled in the art, no further detailed description thereof will be included herein.

[0060] Next, referring to Fig. 6, the operation of the organic EL display panel according to the second embodiment of the present invention will be described.

[0061] As shown in Fig. 6, first, when R data voltages corresponding to pixel circuits 212 connected to scan line X_m are applied from data driver 230, switching elements MR_1 to MR_n and switching elements PG_1 to PG_n and PB_1 to PB_n are turned on by switching signals H_R, P_G , and P_B and then the selection signal for selecting scan line X_m is applied. In this way, pixel circuits 212 connected to scan line X_m operate with R data voltages applied to data lines $Y_1, Y_4, \dots, Y_{3n-2}$ and data lines $Y_2, Y_3, Y_5, Y_6, \dots, Y_{3n-1}$ and Y_{3n} are precharged to precharge voltages V_{pre} with the parasitic capacitors.

[0062] Next, when the G data voltages are applied from data driver 230, switching elements MR_1 to MR_n and PG_1 to PG_n are turned off, and switching elements MG_1 to MG_n are turned on by switching signals H_R and P_G of high level, and switching signal H_G of low level. In this way, pixel circuits 212 connected to scan line X_m and data lines $Y_2, Y_5, \dots$,

Y_{3n-1} operate with the G data voltages applied to those data lines and data lines $Y_3, Y_6, \dots, Y_{3n}$ are still precharged to precharge voltages V_{pre} with the parasitic capacitors.

[0063] Next, when the B data voltages are applied from data driver 230, switching elements MG_1 to MG_n and switching elements PB_1 to PB_n are turned off, and switching elements MB_1 to MB_n are turned on by switching signals H_G and P_B of high level and switching signal H_B of a low signal. In this way, pixel circuits 212 connected to scan line X_m and data lines $Y_3, Y_6, \dots, Y_{3n}$ operate with the B data voltages applied to those data lines.

[0064] As in the second embodiment of the present invention where the R, G, and B data voltages are applied sequentially for the time scan line X_m is selected, the data lines $Y_2, Y_3, Y_5, Y_6, \dots, Y_{3n-1}$, and Y_{3n} are precharged to precharge voltages V_{pre} during the application of the R data voltages to data lines $Y_1, Y_4, \dots, Y_{3n-2}$. Accordingly, since transistors M2 are not turned on by the differences between the precharge voltages stored in capacitors C1 and precharge voltages V_{pre} , capacitors C1 can be kept with precharge voltages V_p continuously.

[0065] Therefore, the problem previously described does not occur that transistors M2 are not turned on by applied data voltages due to changed voltages of capacitors C1.

[0066] Although, in the second embodiment of the present invention, it is described that the data voltages are outputted per R, G, and B sequentially and demultiplexer 240 works as 1:3 DEMUX, the present invention is not limited to this. N data lines may be formed as one group and the data voltages corresponding to respective groups may be outputted sequentially. In this way, the demultiplexer works as 1:N DEMUX to distribute the data voltages inputted to the respective groups to the corresponding the data lines out of the N data lines. Since alternative configurations and driving signals in accordance with the teachings of the present invention will be apparent those skilled in the art, no further detailed description thereof will be included herein.

[0067] Next, the case where the data driver is configured by using a shift register will be described.

[0068] First, referring to Fig. 7 and Fig. 8, an organic EL display and a driving method thereof will be described.

[0069] Fig. 7 shows an organic EL display according to a third embodiment of the present invention, and Fig. 8 shows timing diagrams of the organic EL display according to the third embodiment of the present invention.

[0070] As shown in Fig. 7, the organic EL display according to the third embodiment of the present invention includes organic EL display panel 310, scan driver 320, data driver 330, and precharge means 340.

[0071] Organic EL display panel 310 includes a plurality of data lines Y_1 to Y_n transmitting the data voltages representing image signals, a plurality of scan lines X_1 to X_M transmitting selection signals, and a plurality of pixel circuits 312. Pixel circuits 312 include pixel circuits 112 according to the first embodiment and all the pixel circuits capable of being modified in the first embodiment of the present invention.

[0072] Scan driver 320 applies the selection signals to scan lines X_1 to X_M to control on/off of thin film transistors M3 of pixel circuits 312.

[0073] Data driver 330 includes shift register 332, a plurality of OR gates OR_1 to OR_N , and data voltage switching elements HSW_1 to HSW_N made of PMOS transistors.

[0074] Shift register 332 outputs control signals H_1 to H_N for controlling on/off of switching elements HSW_1 to HSW_N , and these signals H_1 to H_N are inputted to respective OR gates OR_1 to OR_N together with an OE signal from a controller (not shown). The OE signal is a control signal for selecting the data lines after the data of image signals V_{sig} is changed, and the respective outputs of OR gates OR_1 to OR_N become switching signals for turning on/off switching elements HSW_1 to HSW_N .

[0075] The image signals V_{sig} are sequentially sampled by switching signals S_1 to S_N of shift register 332 to be applied to respective data lines Y_1 to Y_N . In detail, one ends of switching elements HSW_1 to HSW_N are connected to one ends of data lines Y_1 to Y_N , and the other ends of switching elements HSW_1 to HSW_N are connected to image signal lines 334 transmitting image signals V_{sig} . Switching elements HSW_1 to HSW_N sequentially apply the image signals to respective data lines Y_1 to Y_N , responding to switching signals S_1 to S_N , respectively.

[0076] Precharge means 340 are connected to the other ends of data lines Y_2 to Y_N and include switching elements PSW_2 to PSW_N composed of PMOS transistors for precharging. Switching elements PSW_2 to PSW_N apply precharge voltage V_{pre} to data lines Y_2 to Y_N at the same time in response to precharge control signal PC from the controller. Precharge voltage V_{pre} has a value equal to 'precharge voltage V_p - threshold voltage V_{TH2} ' or a value further from image signals V_{sig} than that, compared with precharge voltage V_p applied to capacitors C1.

[0077] In the third embodiment of the present invention, although switching elements HSW_1 to HSW_N and PSW_1 to PSW_N are respectively provided at both ends of data lines Y_1 to Y_N , they may also be provided at either end of data lines Y_1 to Y_N .

[0078] In addition, although transistors M1, M2, M3, and M4, switching elements HSW_1 to HSW_N , and switching elements PSW_2 to PSW_N have been described to be composed of PMOS transistors, the present invention is not limited to this but they may be composed of NMOS transistors or both of PMOS and NMOS transistors. Since alternative circuit configurations and driving signals in accordance with the teachings of the present invention will be apparent those skilled in the art, no further detailed description thereof will be included herein.

[0079] Referring to Fig. 8, an operation of the organic EL display according to the third embodiment of the present

invention will be described in the following.

[0080] As shown in Fig. 8, first, switching element HSW_1 and switching elements PSW_2 to PSW_N are turned on by switching signal S_1 and control signals PC of low level, and then the selection signal for selecting scan line X_m are applied. Then, organic EL device OLED of pixel circuit 312 connected to scan line X_m and data line Y_1 is driven with the data voltage that is sampled from image signal V_{sig} by switching element HSW_1 , and data lines Y_2 to Y_N are precharged to precharge voltages V_{pre} by the parasitic capacitors.

[0081] Next, the control signals are inverted to turn off switching elements PSW_2 to PSW_N , and thereby, data lines Y_2 to Y_N are floated to be kept with precharge voltage V_{pre} until the data voltages are applied thereto. Thereafter, shift register 332 shifts and outputs the selection signal to turn on switching elements HSW_2 to HSW_N sequentially to apply image signal V_{sig} to data lines Y_2 to Y_N , and thereby, driving organic EL device OLED.

[0082] In this way, since data lines Y_2 to Y_N are kept with precharge voltages V_{pre} until the data voltages are applied, transistors M2 are not turned on by differences between precharge voltages V_p stored in capacitors C1 and precharge voltages V_{pre} at the time of selecting scan line X_m . Accordingly, capacitors C1 are kept with precharge voltages V_p continuously. Therefore, the case where transistors M2 are not turned on at the time the data voltages are applied due to the change of the voltages of capacitors C1, as described before, does not occur.

[0083] However, in case of driving switching elements PSW_2 to PSW_N at the same time with a single signal as in the third embodiment of the present invention, as the size of the panel and resolution thereof become larger, resistances of the signal lines and gate capacitances of the thin film transistors are increased accordingly, thereby, increasing RC delays.

[0084] Since rising time and falling time of precharge control signal PC becomes larger due to such RC delay, the time difference between the leading edge of switching signal H_1 and the leading edge of the switching signal H_2 must become larger. Thus, since pulse widths of switching signals H_1 to H_N must be increased, the speed of clock must be decreased, and in the end, this limits the frequency of data driver 330.

[0085] To solve such problem, switching elements for precharging may be driven respectively, and in the following, such an embodiment will be described with reference to Figs. 9 and 10.

[0086] Fig. 9 shows an organic EL display according to a fourth embodiment of the present invention, and Fig. 10 shows a timing diagram of the organic EL display according to the fourth embodiment of the present invention.

[0087] As shown in Fig. 9, the organic EL display according to the fourth embodiment of the present invention includes organic EL display panel 410, scan driver 420, data driver 430, and precharge means 440.

[0088] Organic EL display panel 410 and scan driver 420 of the fourth embodiment are the same as organic EL display panel 310 and scan driver 320 of the third embodiment, and pixel circuits 412 of organic EL display panel 410 include the pixel circuits according to the first embodiment and all the pixel circuits capable of being modified in the first embodiment of the present invention.

[0089] Data driver 430 includes shift register 432, switching elements for data voltage HSW_1 to HSW_N , and OR gate OR_1 to OR_N .

[0090] Shift register outputs control signals H_1 to H_N for controlling switching elements HSW_1 to HSW_N sequentially, and these control signals are inputted to respective OR gates OR_1 to OR_N together with an OE signal from a controller (not shown). Respective outputs of OR gates OR_1 to OR_N become switching signals S_1 to S_N for turning on/off switching elements HSW_1 to HSW_N .

[0091] Image signals V_{sig} are sampled sequentially by the switching signals of shift register 432 to be applied to respective data lines Y_1 to Y_N . In detail, one ends of data lines Y_1 to Y_N are respectively connected to one ends of switching elements HSW_1 to HSW_N , and the other ends of switching elements HSW_1 to HSW_N are respectively connected to image signal line 434 for transmitting image signals V_{sig} . Switching elements HSW_1 to HSW_N sequentially transmit the image signals to respective data lines Y_1 to Y_N in response to switching signals S_1 to S_N .

[0092] Precharge means 440 include switching elements for precharging PSW_2 to PSW_N and a plurality of precharge control signal generators 442.

[0093] Precharge control signal generators 442 respectively receive control signals H_1 to H_{N-1} from shift register 432 and previous precharge control signals P_1 to P_{N-1} to generate precharge control signals P_2 to P_N . Precharge control signal P_1 is a signal always high. Precharge control signal generators 442 are composed of AND gates in the fourth embodiment of the present invention.

[0094] Switching elements PSW_2 to PSW_N transmit precharge voltages V_{pre} to data lines Y_2 to Y_N in response to precharge control signals P_2 to P_N . Such precharge control signal V_{pre} is equal to 'precharge voltage V_p - threshold voltage V_{TH2} ' or further from voltage V_{sig} than that, compared with the precharge voltage applied to capacitor C1.

[0095] Now, the operation of the organic EL display according to the fourth embodiment of the present invention will be described with reference to Fig. 10.

[0096] As shown in Fig. 10, precharge control signals P_2 to P_N become low level by control signal H_1 of low level, control signal H_2 to H_N of high level, and control signal P_1 of high level. Switching elements HSW_1 and switching elements PSW_2 to PSW_N are turned on by these signals and the selection signal for selecting scan line X_m is applied. Then,

organic EL device OLED of pixel circuit 412 connected to scan line X_m and data line Y_1 are driven by the data voltage sampled by switching element HSW_1 , and data lines Y_2 to Y_N are precharged to precharge voltages V_{pre} by the parasitic capacitors.

[0097] Next, when control signal H_1 becomes high level and control signal H_2 becomes low level by shift register 432, control signal P_2 becomes high level, and control signals P_3 to P_N are kept with low level continuously. Switching element PSW_2 is turned off, and switching element HSW_2 is turned on by such signals to transmit the data voltage to data line Y_2 , and switching elements PSW_3 to PSW_N are turned on continuously to transmit the precharge voltages to data lines Y_3 to Y_N .

[0098] As above, switching elements HSW_2 to HSW_N are sequentially turned on, and switching elements PSW_2 to PSW_N are sequentially turned off, thereby, applying the data voltages to data lines Y_2 to Y_N , and the data lines are charged to precharge voltage V_{pre} until the data voltages are applied to them.

[0099] In this way, since data lines Y_2 to Y_N are kept with precharge voltages V_{pre} until the data voltages sampled from image signal V_{sig} are applied thereto, transistor M2 is not turned on by difference between precharge voltage V_p stored in capacitor C1 at the time scan line X_{m-1} is selected and precharge voltage V_{pre} , and thus, capacitor C1 can be kept with precharge voltage V_p .

[0100] Therefore, the case where transistors M2 are not turned on at the time the data voltages are applied due to the change of the voltages of capacitors C1, as described before, does not occur.

[0101] Meanwhile, as shown in Fig. 11, when shift register 432 which outputs partially overlapped control signals H_1 to H_N is used, the problem described above may occur. That is, data line Y_2 is connected to the image signal line that transmits image signal V_{sig} , by control signal H_2 , while the data are written to data line Y_1 . In this case, when image signal V_{sig} becomes a value corresponding to data line Y_2 and data line Y_2 has to be written on, the data written to data line Y_2 for the time data line Y_1 is written on may cause a problem that transistor M2 is not turned on as described above.

[0102] Embodiments of the case that shift register 432 which outputs partially overlapped control signals H_1 to H_N is used will be described in detail with reference to Figs. 11 to 13.

[0103] Fig. 11 is a timing diagram of organic EL displays according to a fifth and a sixth embodiment of the present invention. Figs. 12 and 13 are diagrams to illustrate precharge control signal generators in the organic EL displays according to the fifth and the sixth embodiments of the present invention.

[0104] Accordingly, when precharge control signal generators 442 as shown in Fig. 12 generate precharge control signals P_1 to P_N , precharge control signals are generated as shown in Fig. 11 in the fifth embodiment of the present invention. Now, precharge control signal generator 442 for generating precharge control signal P_n applied to data line Y_n will be described.

[0105] Precharge control signal generator 442 for generating precharge control signal P_n includes an inverter, an OR gate, and an AND gate. The OR gate receives a signal that the inverter outputs in response to control signal H_{n+1} corresponding to the next data line Y_{n+1} and a control signal corresponding to the present data line Y_n . Output of the OR gate and previous precharge control signal P_{n-1} are inputted together to the AND gate to generate precharge control signal P_n .

[0106] Precharge control signals P_1 to P_N generated as above are as shown in Fig. 11. For example, while the corresponding data voltage is applied to data line Y_1 by control signal H_1 , a time interval that switching element HSW_2 is turned on by control signal H_2 of low level is generated. In this case, until image signal V_{sig} becomes a value corresponding to data line Y_2 , switching element PSW_2 may be turned on by precharge control signal P_2 according to the fifth embodiment to transmit precharge voltage V_{pre} .

[0107] As above, in case precharge voltage V_{pre} is applied to data line Y_2 in the interval that switching elements HSW_2 and PSW_2 are turned on, precharge voltage V_{pre} has to be set so that the voltage applied to data line Y_2 and determined by image signal V_{sig} and precharge voltage V_{pre} is equal to 'precharge voltage V_p - threshold voltage V_{TH2} ' or further from image signal V_{sig} than that.

[0108] According to such fifth embodiment, the driving voltages of switching elements PSW_2 and HSW_2 may increase as the difference between precharge voltage V_{pre} and image signal V_{sig} increases. When the driving voltages are increased, there is a problem that power consumption is also increased.

[0109] Therefore, a shift register whose outputs do not overlap each other is configured in a sixth embodiment by adjusting outputs of the shift register in the fifth embodiment.

[0110] As shown in Fig. 13, in case switching elements HSW_1 to HSW_N are PMOS transistors, the shift register whose outputs do not overlap may be provided by an OR operation of the two adjacent outputs of shift register 432 with OR gates.

[0111] For example, the result of performing an OR-operation of outputs H_1 and H_2 of shift register 432 is made to be new output H_1' . That is, when both of two outputs H_1 and H_2 are low levels, output H_1' of the OR gate becomes low level, and also, when both of outputs H_2 and H_3 are low levels, output H_2' becomes low level, and thereby, it is possible to form a shift register without overlapping the outputs.

[0112] Although the switching elements have been described with using PMOS transistors in the first to the sixth embodiments, the present invention is not limited to this but may use NMOS transistors, CMOS transistors, or a com-

ination thereof. Since alternative circuit configurations and driving signals in accordance with the teachings of the present invention will be apparent those skilled in the art, no further detailed description thereof will be included herein.

[0113] In addition, as shown in Fig. 3B, also in the second to the sixth embodiments of the present invention, a separate reset signal is applied to the gate of transistor M4 to drive it to charge capacitor C1 of pixel circuit 112 with precharge voltage Vp.

[0114] According to the present invention as described above, by applying precharge voltages Vpre to the data lines before the data voltages are applied thereto, it is possible to prevent the charge redistribution of capacitors C1 that is generated due to turning on of the switching elements with precharge voltage Vp charged in capacitors C1 of the pixel circuits when the previous scan line is selected and the previous data voltages stored in the parasitic capacitors of the data lines. Therefore, it is possible to solve the problem of poor images caused by the charge redistribution of capacitors C1.

[0115] In addition, although the pixel circuits with four transistors have been described as an example in the embodiments of the present invention, the present invention is not limited to this but is applicable to all of the pixel circuits that precharge voltages Vp are applied to. Furthermore, although the organic EL display has been described as an example in the embodiments of the present invention, the present invention is not limited to this but is applicable to all of the displays applying precharge voltages Vp to capacitors C1 provided in the pixel circuits. In other words, in case the pixel circuits of the displays include transistors driven by the signals applied through the gate lines and the data lines and transistors for applying precharge voltages Vp, it is possible to improve the poor images by applying precharge voltages Vpre to the data lines, as described in the embodiments of the present invention.

[0116] The various embodiments of the present invention have been defined in the appended claims.

[0117] Where technical features mentioned in any claim are followed by reference signs, those reference signs have been included for the sole purpose of increasing the intelligibility of the claims and accordingly, such reference signs do not have any limiting effect on the scope of each element identified by way of example by such reference signs.

Claims

1. An OLED display comprising:

a plurality of data lines transmitting data voltages representing image signals;
 a plurality of scan lines transmitting selection signals;
 a plurality of pixel circuits provided in pixel areas, each pixel area being defined by two adjacent data lines and two adjacent scan lines, each pixel circuit having first switching elements responding to the selection signals applied to the scan lines to transmit the data voltages applied to the data lines, first thin film transistors supplying currents to lighting emitting devices in correspondence to the data voltages inputted to gates thereof through the first switching elements, capacitors for maintaining the data voltages said OLED display being **characterised in that** said pixel circuit further comprises second switching elements applying first precharge voltages to the capacitors of the pixels of a predetermined scan line in response to control signals while the selection signal is applied to the previous scan line of said predetermined scan line
 and said OLED display comprising a data driver adapted to divide the data lines into a plurality of groups and to selectively apply the corresponding data voltages to the respective groups, the group including at least one data line; and a precharge means adapted to second precharge voltages to the data lines of at least one group before the selection signal for selecting said scan line is applied and adapted to stop the application of the second precharge voltages when the corresponding data voltages are applied to the groups.

2. The display of claim 1, wherein the pixel circuits include second thin film transistors of which the gates are connected to the gates of the first thin film transistors and that are diode-connected between the first switching elements and the second switching elements, and wherein the second precharge voltage has a value equal to 'the first-precharge voltage - threshold voltage of the second thin film transistor' or a value further from the data voltage.

3. The display of claim 1, wherein the control signals are selection signals applied to a previous scan line.

4. The display of claim 1, wherein the control signals are separate reset signals.

5. The display of claim 1, wherein the second precharge voltages have constant values.

6. The display of claim 1, wherein the data driver divides the data lines into a plurality of groups to selectively apply the data voltages to the respective groups by group unit; and

the precharge means includes a demultiplexer applying the data voltages selectively applied from the data driver to corresponding data lines and applying second precharge voltages to the data lines of at least one group out of the groups before the selection signals for selecting a scan line are applied to the scan line.

7. The display of claim 6, wherein the demultiplexer includes:

a plurality of third switching elements, each connected to the data line, and turned on when data voltage corresponding to the connected data line is applied; and
a plurality of fourth switching elements, each connected between signal for the second precharge voltage and data line of at least one group, and turned on before the selection signal is applied to the scan line connected to the pixel circuit and turned off when the corresponding data voltage is applied to the connected data line.

8. The display of claim 7, wherein the data driver divides the data lines into three groups to which the data voltages corresponding to first to third colors are applied, thereby outputs the data voltages corresponding to the first to the third colors sequentially, and
wherein the plurality of fourth switching elements are connected to the data lines corresponding to at least one color of the first to the third colors.

9. The display of claim 1, wherein the data driver applies the data voltages to the data lines sequentially; and the precharge means applies second precharge voltages to the data lines before the selection signals for selecting a scan line are applied to the scan line and stops the application of the second precharge voltages simultaneously when the data voltage is applied to any one of the data lines to which the precharge voltages are applied.

10. The display of claim 9, wherein the data driver includes:

a plurality of third switching elements, each connected between at least one signal line transmitting image signals representing the data voltages and the data lines, to perform switching operations when the image signals have values corresponding to the data lines; and
a shift register sequentially outputting a plurality of switching signals for driving the third switching elements, respectively,
wherein the precharge means includes a plurality of fourth switching elements connected between a second signal line for transmitting the second precharge voltages and the data lines, and turned on simultaneously before the selection signals for selectin a scan line are applied to the scan line connected to the pixel circuits and turned off simultaneously when the data voltage is applied to any one of the connected data lines.

11. The display of claim 10, wherein the fourth switching elements are connected to at least second to last data lines of the data lines, respectively.

12. The display of claim 10, wherein, when both of two adjacent outputs of the shift register have levels for driving the third switching elements, the switching signals are changed into levels for driving the third switching elements.

13. The display of claim 1, wherein the data driver applies the data voltages to the data lines sequentially; and the precharge means applies the second precharge voltages to the data lines before the selection signals for selecting scan lines are applied to the scan lines connected to the pixel circuits, and sequentially stops the application of the second precharge voltages to the respective data lines before the data voltages are applied to the respective data lines.

14. The display of claim 13, wherein the data driver includes a plurality of third switching elements connected between at least one first signal line for transmitting image signals representing data voltages and the data lines, to perform switching operations when the image signals have values corresponding to the data lines; and a shift register sequentially outputting a plurality of switching signals for driving the third switching elements, respectively, wherein, the precharge means includes a plurality of fourth switching elements connected between a second signal line for transmitting the precharge voltages and the data lines; and a plurality of precharge control signal generators receiving precharge control signals for driving the fourth switching elements connected to the previous data lines and the switching signals for driving the third switching elements connected to the previous data lines, and generating precharge control signals for driving the fourth switching elements connected to the present data lines.

15. The display of claim 14, wherein the precharge control signal generators are composed of AND gates receiving the

switching signals for driving the third switching elements connected to the previous data lines and the precharge control signals for driving the fourth switching elements connected to the previous data lines.

16. The display of claim 14, wherein the precharge control signal generators generate precharge control signals for turning off the fourth switching elements connected to the present data lines when switching signals for turning on the third switching elements connected to next data lines are applied.

17. The display of claim 16, wherein the precharge control signal generators include OR gates receiving inverted values of switching signals for driving the third switching elements connected to next data lines and switching signals for driving the third switching elements connected to the present data lines as inputs; and AND gates receiving outputs of the OR gates and previous precharge control signals as inputs, wherein the outputs of the AND gates become precharge control signals.

18. The display of claim 14, wherein, when both of the two adjacent outputs of the shift register have levels for driving the third switching elements, the switching signals are changed into levels for driving the third switching elements.

19. A method of driving an OLED display comprising a plurality of data lines transmitting data voltages; a plurality of scan lines transmitting selection signals; and a plurality of pixel circuits provided in pixel areas each pixel area being defined by two adjacent data lines and two adjacent scan lines, and having first thin film transistors supplying currents to lighting emitting devices and capacitors for maintaining the data voltages, the method being **characterised by** the step of

(a) precharging the capacitor of the pixel circuit connected to i-th scan line with the first precharge voltage while selection signal is applied to (i-1)th scan line:

(b) applying second precharge voltages to the data lines before selection signal is applied to the i-th scan line; and
(c) stopping application of the second precharge voltage when the data voltages are applied to the data lines to which the second precharge voltages have been applied, applying corresponding data voltages to the respective groups of the data lines which consist of at least one data line.

20. The method of claim 19, wherein, in the step (b), the precharge voltages are applied to the data lines at the same time.

21. The method of claim 19, wherein, in the step (b), the second precharge voltages are applied to the data lines sequentially.

22. The method of claim 19, wherein, in the step (c), application of the second precharge voltages is stopped for all data lines before data voltages are applied to any one of groups to which the second precharge voltages have been applied.

23. The method of claim 19, wherein, in the step (c), before data voltages are sequentially applied to groups to which the second precharge voltages have been applied, applications of the second precharge voltages to the respective groups are stopped sequentially.

24. The method of claim 19, wherein the second precharge voltages have constant values.

25. The method of claim 19, wherein each of the pixel circuits includes a switching element connected between the capacitor and the first precharge voltage, wherein, in the step (a), the switching elements are driven by selection signal applied to (i-1)-th scan line to charge the capacitors with the first precharge voltages.

26. The method of claim 19, wherein each of the pixel circuits includes a switching element connected between the capacitor and the first precharge voltage, wherein, in the step (a), the capacitors are charged with the first precharge voltages by separate reset signals.

Patentansprüche

1. Eine OLED-Anzeige, die Folgendes umfasst:

eine Vielzahl von Datenleitungen, die Datenspannungen übertragen, welche Bildsignale darstellen,
 eine Vielzahl von Abtastleitungen, die Wählsignale übertragen,
 eine Vielzahl von Pixel-Schaltungen, die in Pixelbereichen bereitgestellt sind, wobei jeder Pixelbereich durch
 zwei benachbarte Datenleitungen und zwei benachbarte Abtastleitungen bestimmt wird und jede Pixel-Schal-
 tung erste Schaltelemente hat, die auf die Wählsignale antworten, welche an die Abtastleitungen angelegt
 werden, um die Datenspannungen zu übertragen, die an die Datenleitungen angelegt werden, wobei erste
 Dünnschichttransistoren Ströme an Beleuchtungs-Emittierende-Voxrichtungen zuführen, entsprechend den
 Datenspannungen, die in Gates davon durch die ersten Schaltelemente eingegeben werden,
 Kondensatoren zur Aufrechterhaltung der Datenspannungen,
 wobei die OLED-Anzeige **dadurch gekennzeichnet ist, dass** die Pixel-Schaltung weiter zweite Schaltelemente
 umfasst, die erste Vorladespannungen an die Kondensatoren der Pixel einer vordefinierten Abtastleitung als
 Reaktion auf Steuersignale anlegen, während das Wählsignal an die Abtastleitung angelegt wird, die der vor-
 definierten Abtastleitung vorangeht,
 und wobei die OLED-Anzeige weiter einen Datentreiber umfasst, der ausgebildet ist, um die Datenleitungen in
 eine Vielzahl von Gruppen zu unterteilen und um die entsprechenden Datenspannungen selektiv an die jewei-
 ligen Gruppen anzulegen, wobei die Gruppe mindestens eine Datenleitung einschließt, und ein Vorlademittel,
 das ausgebildet ist, um zweite Vorladespannungen an die Datenleitungen mindestens einer Gruppe anzulegen,
 bevor das Wählsignal zur Auswahl der Abtastleitung angelegt wird, und das ausgebildet, um das Anlegen der
 zweiten Vorladespannungen abubrechen, wenn die entsprechenden Datenspannungen an die Gruppen an-
 gelegt werden.

2. Die Anzeige gemäß Anspruch 1, wobei die Pixel-Schaltungen zweite Dünnschichttransistoren einschließen, deren
 Gates mit den Gates der ersten Dünnschichttransistoren verbunden sind und die als Diode zwischen den ersten
 Schaltelementen und den zweiten Schaltelementen geschaltet sind und wobei die zweite Vorladespannung einen
 Wert gleich der "ersten Vorladespannung - Schwellenspannung des zweiten Dünnschichttransistors" oder einen
 Wert weiter entfernt von der Datenspannung hat.

3. Die Anzeige gemäß Anspruch 1, wobei die Steuersignale Wählsignale sind, die an eine vorhergehende Abtastleitung
 angelegt werden.

4. Die Anzeige gemäß Anspruch 1, wobei die Steuersignale separate Rücksetzsignale sind.

5. Die Anzeige gemäß Anspruch 1, wobei die zweiten Vorladespannungen konstante Werte haben.

6. Die Anzeige gemäß Anspruch 1, wobei der Datentreiber die Datenleitungen in eine Vielzahl von Gruppen unterteilt,
 um die Datenspannungen selektiv an die jeweiligen Gruppen je Gruppeneinheit anzulegen, und
 das Vorlademittel einen Demultiplexer einschließt, der die Datenspannungen, die vom Datentreiber selektiv an
 entsprechende Datenleitungen angelegt werden, anlegt und zweite Vorladespannungen an die Datenleitungen
 mindestens einer Gruppe der Gruppen anlegt, bevor die Wählsignale zur Auswahl einer Abtastleitung an die Ab-
 tastleitung angelegt werden.

7. Die Anzeige gemäß Anspruch 6, wobei der Demultiplexer Folgendes einschließt:

eine Vielzahl dritter Schaltelemente, die jeweils mit der Datenleitung verbunden sind, und eingeschaltet werden,
 wenn die Datenspannung, die der verbundenen Datenleitung entspricht, angelegt wird, und
 eine Vielzahl vierter Schaltelemente, die jeweils zwischen dem Signal für die zweite Vorladespannung und der
 Datenleitung mindestens einer Gruppe verbunden sind, und eingeschaltet werden, bevor das Wählsignal an
 die mit der Pixel-Schaltung verbundene Abtastleitung angelegt wird, und ausgeschaltet werden, wenn die
 entsprechende Datenspannung an die verbundene Datenleitung angelegt wird.

8. Die Anzeige gemäß Anspruch 7, wobei der Datentreiber die Datenleitungen in drei Gruppen unterteilt, an welche
 die Datenspannungen, die ersten bis dritten Farben entsprechen, angelegt werden, wobei dabei die Datenspan-
 nungen nacheinander ausgegeben werden, die den ersten bis dritten Farben entsprechen, und
 wobei die Vielzahl vierter Schaltelemente mit den Datenleitungen verbunden ist, die mindestens einer Farbe der
 ersten bis dritten Farbe entsprechen.

9. Die Anzeige gemäß Anspruch 1, wobei der Datentreiber die Datenspannungen nacheinander an die Datenleitungen
 anlegt, und

das Vorlademittel zweite Vorladespannungen an die Datenleitungen anlegt, bevor die Wählsignale zur Auswahl einer Abtastleitung an die Abtastleitung angelegt werden, und das Anlegen der zweiten Vorladespannungen gleichzeitig beendet, wenn die Datenspannung an eine beliebige der Datenleitungen angelegt wird, an die die Vorladespannungen angelegt werden.

10. Die Anzeige gemäß Anspruch 9, wobei der Datentreiber Folgendes einschließt:

eine Vielzahl dritter Schaltelemente, die jeweils zwischen mindestens einer Signalleitung verbunden sind, wobei Bildsignale gesendet werden, welche die Datenspannungen darstellen, und den Datenleitungen, zur Durchführung von Schaltvorgängen, wenn die Bildsignale Werte haben, die den Datenleitungen entsprechen, und ein Schieberegister, das nacheinander eine Vielzahl von Schaltsignalen jeweils zum Ansteuern der dritten Schaltelemente ausgibt, wobei das Vorlademittel eine Vielzahl vierter Schaltelemente einschließt, die zwischen einer zweiten Signalleitung zur Übertragung der zweiten Vorladespannungen und den Datenleitungen verbunden sind und gleichzeitig eingeschaltet werden, bevor die Wählsignale zur Auswahl einer Abtastleitung an die Abtastleitung angelegt werden, die mit den Pixel-Schaltungen verbunden ist, und gleichzeitig ausgeschaltet werden, wenn die Datenspannung an irgendeine der verbundenen Datenleitungen angelegt wird.

11. Die Anzeige gemäß Anspruch 10, wobei die vierten Schaltelemente jeweils mit mindestens der zweiten bis letzten der Datenleitungen verbunden sind.

12. Die Anzeige gemäß Anspruch 10, wobei, wenn beide der benachbarten Ausgaben des Schieberegisters Pegel zum Ansteuern der dritten Schaltelemente haben, die Schaltsignale auf Pegel zum Ansteuern der dritten Schaltelemente verändert werden.

13. Die Anzeige gemäß Anspruch 1, wobei der Datentreiber die Datenspannungen nacheinander an die Datenleitungen anlegt; und
das Vorlademittel die zweiten Vorladespannungen an die Datenleitungen anlegt, bevor die Wählsignale zur Auswahl der Abtastleitungen an die mit den Pixel-Schaltungen verbundenen Abtastleitungen angelegt werden, und das Anlegen der zweiten Vorladespannungen an die jeweiligen Datenleitungen stoppt, bevor die Datenspannungen an die jeweiligen Datenleitungen angelegt werden.

14. Die Anzeige gemäß Anspruch 13, wobei der Datentreiber eine Vielzahl dritter Schaltelemente einschließt, die zwischen mindestens einer ersten Signalleitung zur Übertragung von Bildsignalen, welche Datenspannungen darstellen, und den Datenleitungen verbunden sind, um Schaltvorgänge durchzuführen, wenn die Bildsignale Werte haben, die den Datenleitungen entsprechen, und ein Schieberegister, das sequentiell eine Vielzahl von Schaltsignalen, um die dritten Schaltelemente jeweils anzusteuern, ausgibt, wobei das Vorlademittel eine Vielzahl vierter Schaltelemente einschließt, die zwischen einer zweiten Signalleitung zur Übertragung der Vorladespannungen und den Datenleitungen verbunden ist, und eine Vielzahl von Vorlade-Steuersignalgebern, die Vorlade-Steuersignale zum Ansteuern der vierten Schaltelemente empfangen, die mit den vorhergehenden Datenleitungen verbunden sind, und die Schaltsignale zum Ansteuern der dritten Schaltelemente, die mit den vorhergehenden Datenleitungen verbunden sind, und zum Erzeugen von Vorlade-Steuersignalen zum Ansteuern der vierten Schaltelemente, die mit den gegenwärtigen Datenleitungen verbunden sind.

15. Die Anzeige gemäß Anspruch 14, wobei die Vorlade-Steuersignalgeber aus UND-Gliedern bestehen, die die Steuersignale zum Ansteuern der dritten Schaltelemente empfangen, welche mit den vorhergehenden Datenleitungen und den Vorlade-Steuersignalen verbunden sind, um die vierten Schaltelemente anzutreiben, die mit den vorhergehenden Datenleitungen verbunden sind.

16. Die Anzeige gemäß anspruch 14, wobei die Vorlade-Steuersignalgeber Vorlade-Steuersignale erzeugen, um die vierten Schaltelemente auszuschalten, die mit den gegenwärtigen Datenleitungen verbunden sind, wenn Schaltsignale zum Einschalten der dritten Schaltelemente, die mit den nächsten Datenleitungen verbunden sind, angelegt werden.

17. Die Anzeige gemäß Anspruch 16, wobei die Vorlade-Steuersignalgeber ODER-Glieder einschließen, die Kehrwerte von Schaltsignalen zum Ansteuern der dritten Schaltelemente als Eingaben empfangen, die mit nächsten Datenleitungen verbunden sind, und Schaltsignale zum Ansteuern der dritten Schaltelemente, die mit den gegenwärtigen Datenleitungen verbunden sind; und UND-Glieder, die Ausgaben der ODER-Glieder und frühere Vorlade-Steuersignale als Eingaben empfangen;

wobei die Ausgaben der UND-Glieder zu Vorlade-Steuersignalen werden.

18. Die Anzeige gemäß Anspruch 14, wobei, wenn beide der zwei benachbarten Ausgaben des Schieberegisters Pegel zum Ansteuern der dritten Schaltelemente haben, die Schaltsignale auf Pegel zum Ansteuern der dritten Schaltelemente verändert werden.

19. Ein Verfahren zum Ansteuern einer OLED-Anzeige, die eine Vielzahl von Datenleitungen zur Übertragung von Datenspannungen umfasst, eine Vielzahl von Abtastleitungen, die Wählsignale übertragen, und eine Vielzahl von Pixel-Schaltungen, die in Pixelbereichen bereitgestellt werden, wobei jeder Pixelbereich durch zwei benachbarte Datenleitungen und zwei benachbarte Abtastleitungen bestimmt wird, und mit ersten Dünnschichttransistoren, die Ströme an Beleuchtungs-Emittierende-Vorrichtungen liefern, und Kondensatoren zur Aufrechterhaltung der Datenspannungen, wobei das Verfahren **gekennzeichnet ist durch** den Schritt des

(a) Vorladens des Kondensators der Pixel-Schaltung, der mit der i-ten Abtastleitung verbunden ist, mit der ersten Vorladespannung, während das Wählsignal an die (i-1)-te Abtastleitung angelegt wird,

(b) Anlegens der zweiten Vorladespannungen an die Datenleitungen, bevor das Wählsignal an die i-te Abtastleitung angelegt wird, und

(c) Beendens des Anlegens der zweiten Vorladespannung, wenn die Datenspannungen an die Datenleitungen angelegt werden, an welche die zweiten Vorladespannungen angelegt wurden, wobei entsprechende Datenspannungen an die jeweiligen Gruppen der Datenleitungen angelegt werden, die aus mindestens einer Datenleitung bestehen.

20. Das Verfahren gemäß Anspruch 19, wobei in Schritt (b) die Vorladespannungen gleichzeitig an die Datenleitungen angelegt werden.

21. Das Verfahren gemäß Anspruch 19, wobei in Schritt (b) die zweiten Vorladespannungen nacheinander an die Datenleitungen angelegt werden.

22. Das Verfahren gemäß Anspruch 19, wobei in Schritt (c) das Anlegen der zweiten Vorladespannungen für alle Datenleitungen gestoppt wird, bevor Datenspannungen an irgendeine der Gruppen angelegt werden, an welche die zweiten Vorladespannungen angelegt wurden.

23. Das Verfahren gemäß Anspruch 19, wobei in Schritt (c), bevor Datenspannungen nacheinander an Gruppen angelegt werden, an welche die zweiten Vorladespannungen angelegt wurden, das Anlegen der zweiten Vorladespannungen an die jeweiligen Gruppen sequentiell gestoppt wird.

24. Das Verfahren gemäß Anspruch 19, wobei die zweiten Vorladespannungen konstante Werte haben.

25. Das Verfahren gemäß Anspruch 19, wobei jeder der Pixel-Schaltungen ein Schaltelement einschließt, das zwischen dem Kondensator und der ersten Vorladespannung verbunden ist, wobei in Schritt (a) die Schaltelemente von einem Wählsignal angesteuert werden, das an die (i-1)-te Abtastleitung angelegt wird, um die Kondensatoren mit den ersten Vorladespannungen aufzuladen.

26. Das Verfahren gemäß Anspruch 19, wobei jeder der Pixel-Schaltung ein Schaltelement einschließt, das zwischen dem Kondensator und der ersten Vorladespannung verbunden ist, wobei in Schritt (a) die Kondensatoren durch separate Rücksetzsignale mit den ersten Vorladespannungen aufgeladen werden.

Revendications

1. Afficheur OLED, comprenant :

une pluralité de lignes de données transmettant des tensions de données représentant des signaux d'image ;
une pluralité de lignes de balayage transmettant des signaux de sélection ;
une pluralité de circuits à pixel, prévus dans des zones à pixel, chaque zone à pixel étant définie par deux lignes de données adjacentes et deux lignes de balayage adjacentes, chaque circuit à pixel comprenant des premiers éléments de commutation répondant aux signaux de sélection appliqués aux lignes de balayage, pour

transmettre les tensions de données appliquées aux lignes de données, des premiers transistors à film mince, fournissant des courants à des dispositifs photoémetteurs, en correspondance avec les tensions de données introduites à des grilles de ceux-ci, par les premiers éléments de commutation, des condensateurs pour maintenir les tensions de données, ledit afficheur OLED étant **caractérisé en ce que** ledit circuit à pixel comprend en outre des deuxièmes éléments de commutation, appliquant des premières tensions de précharge aux condensateurs des pixels d'une ligne de balayage prédéterminée, en réponse à des signaux de commande, tandis que le signal de sélection est appliqué à la ligne de balayage précédente de ladite ligne de balayage prédéterminée ;

et ledit afficheur OLED comprenant en outre :

un pilote de données, adapté pour diviser les lignes de données en une pluralité de groupes et appliquer sélectivement les tensions de données correspondantes aux groupes respectifs, le groupe comprenant au moins une ligne de données ; et des moyens de précharge, adaptés pour appliquer des deuxièmes tensions de précharge aux lignes de données d'au moins un groupe, avant que le signal de sélection pour sélectionner ladite ligne de balayage soit appliqué, et adaptés pour stopper l'application des deuxièmes tensions de précharge, lorsque les tensions de données correspondantes sont appliquées aux groupes.

2. Afficheur selon la revendication 1, dans lequel les circuits à pixel comprennent des deuxièmes transistors à film mince, dont les grilles sont connectées aux grilles des premiers transistors à film mince et connectés, par des diodes, entre les premiers éléments de commutation et les deuxièmes éléments de commutation, et dans lequel la deuxième tension de précharge présente une valeur égale à 'la première tension de précharge - la tension de seuil du deuxième transistor à film mince' ou une valeur plus éloignée de la tension de données.

3. Afficheur selon la revendication 1, dans lequel les signaux de commande sont des signaux de sélection appliqués à une ligne de balayage précédente.

4. Afficheur selon la revendication 1, dans lequel les signaux de commande sont des signaux de remise à l'état initial séparés.

5. Afficheur selon la revendication 1, dans lequel les deuxièmes tensions de précharge ont des valeurs constantes.

6. Afficheur selon la revendication 1, dans lequel le pilote de données divise les lignes de données en une pluralité de groupes, de manière à appliquer sélectivement les tensions de données aux groupes respectifs, par unité de groupe ; et

les moyens de précharge comprennent un démultiplexeur, appliquant les tensions de données sélectivement appliquées à partir du pilote de données à des lignes de données correspondantes et appliquant des deuxièmes tensions de précharge aux lignes de données d'au moins un groupe parmi les groupes, avant que les signaux de sélection, pour sélectionner une ligne de balayage, soient appliqués à la ligne de balayage.

7. Afficheur selon la revendication 6, dans lequel le démultiplexeur comprend :

une pluralité de troisièmes éléments de commutation, chacun connecté à la ligne de données, et mis en service lorsque la tension de données correspondant à la ligne de données connectée est appliquée ; et

une pluralité de quatrièmes éléments de commutation, chacun connecté entre le signal pour la deuxième tension de précharge et la ligne de données d'au moins un groupe, et mis en service avant que le signal de sélection soit appliqué à la ligne de balayage connectée au circuit à pixel et mis hors service lorsque la tension de données correspondante est appliquée à la ligne de données connectée.

8. Afficheur selon la revendication 7, dans lequel le pilote de données divise les lignes de données en trois groupes, auxquels les tensions de données correspondant aux première à troisième couleurs sont appliquées, en produisant ainsi les tensions de données correspondant aux première à troisième couleurs séquentiellement, et dans lequel la pluralité de quatrièmes éléments de commutation sont connectés aux lignes de données correspondant à au moins une couleur des première à troisième couleurs.

9. Afficheur selon la revendication 1, dans lequel le pilote de données applique les tensions de données aux lignes de données séquentiellement ; et

les moyens de précharge appliquent des deuxièmes tensions de précharge aux lignes de données, avant que les signaux de sélection, pour sélectionner une ligne de balayage, soient appliqués à la ligne de balayage, et stoppent l'application des deuxièmes tensions de précharge simultanément, lorsque la tension de données est appliquée à

l'une quelconque des lignes de données auxquelles les tensions de précharge sont appliquées.

10. Afficheur selon la revendication 9, dans lequel le pilote de données comprend :

une pluralité de troisième éléments de commutation, chacun connecté entre au moins une ligne de signal, transmettant des signaux d'image représentant les tensions de données et les lignes de données, pour accomplir des opérations de commutation lorsque les signaux d'image ont des valeurs correspondant aux lignes de données ; et
un registre à décalage, fournissant en sortie, séquentiellement, une pluralité de signaux de commutation pour commander les troisième éléments de commutation, respectivement,
dans lequel les moyens de précharge comprennent une pluralité de quatrième éléments de commutation, connectés entre une deuxième ligne de signal pour transmettre les deuxième tensions de précharge et les lignes de données, et mis en service simultanément avant que les signaux de sélection, pour sélectionner une ligne de balayage, soient appliqués à la ligne de balayage connectée aux circuits à pixel, et mis hors service simultanément, lorsque la tension de données est appliquée à l'une quelconque des lignes de données connectées.

11. Afficheur selon la revendication 10, dans lequel les quatrième éléments de commutation sont connectés à au moins des secondes à dernières lignes de données des lignes de données, respectivement.

12. Afficheur selon la revendication 10, dans lequel les sorties adjacentes du registre à décalage ont toutes deux des niveaux pour commander les troisième éléments de commutation, les signaux de commutation sont modifiés en des niveaux pour commander les troisième éléments de commutation.

13. Afficheur selon la revendication 1, dans lequel le pilote de données applique les tensions de données aux lignes de données séquentiellement ; et
les moyens de précharge appliquent les deuxième tensions de précharge aux lignes de données avant que les signaux de sélection, pour sélectionner les lignes de balayage, soient appliqués aux lignes de balayage connectées aux circuits à pixel, et stoppent séquentiellement l'application des deuxième tensions de précharge aux lignes de données respectives, avant que les tensions de données soient appliquées aux lignes de données respectives.

14. Afficheur selon la revendication 13, dans lequel le pilote de données comprend une pluralité de troisième éléments de commutation, connectés entre au moins une première ligne de signal pour transmettre des signaux d'image représentant des tensions de données et les lignes de données, pour effectuer des opérations de commutation lorsque les signaux d'image ont des valeurs correspondant aux lignes de données ; et un registre à décalage, fournissant en sortie, séquentiellement, une pluralité de signaux de commutation pour commander les troisième éléments de commutation, respectivement,
dans lequel les moyens de précharge comprennent une pluralité de quatrième éléments de commutation, connectés entre une deuxième ligne de signal pour transmettre les tensions de précharge et les lignes de données ; et une pluralité de générateurs de signaux de commande de précharge, recevant des signaux de commande de précharge pour commander les quatrième éléments de commutation connectés aux lignes de données précédentes et les signaux de commutation pour commander les troisième éléments de commutation connectés aux lignes de données précédentes, et engendrer des signaux de commande de précharge, pour commander les quatrième éléments de commutation connectés aux présentes lignes de données.

15. Afficheur selon la revendication 14, dans lequel les générateurs de signaux de commande de précharge sont composés de portes logiques ET, recevant les signaux de commutation pour commander les troisième éléments de commutation connectés aux lignes de données précédentes, et les signaux de commande de précharge pour commander les quatrième éléments de commutation connectés aux lignes de données précédentes.

16. Afficheur selon la revendication 14, dans lequel les générateurs de signaux de commande de précharge engendrent des signaux de commande de précharge, pour mettre hors service les quatrième éléments de commutation connectés aux présentes lignes de données, lorsque des signaux de commutation, pour mettre en service les troisième éléments de commutation connectés à des lignes de données suivantes, sont appliqués.

17. Afficheur selon la revendication 16, dans lequel les générateurs de signaux de commande de précharge comprennent des portes logiques OU, recevant des valeurs inversées de signaux de commutation, pour commander les troisième éléments de commutation connectés aux lignes de données suivantes, et des signaux de commutation pour com-

mander les troisièmes éléments de commutation connectés aux présentes lignes de données, en tant qu'entrées ; et des portes logiques ET, recevant des sorties des portes logiques OU et des signaux de commande de précharge précédents, en tant qu'entrées, dans lequel les sorties des portes logiques ET deviennent des signaux de commande de précharge.

18. Afficheur selon la revendication 14, dans lequel, lorsque les deux sorties adjacentes du registre à décalage ont toutes deux des niveaux pour commander les troisièmes éléments de commutation, les signaux de commutation sont modifiés en des niveaux pour commander les troisièmes éléments de commutation.

19. Procédé de commande d'un afficheur OLED comprenant une pluralité de lignes de données transmettant des tensions de données ; une pluralité de lignes de balayage transmettant des signaux de sélection ; et une pluralité de circuits à pixel, prévus dans des zones à pixel, chaque zone à pixel étant définie par deux lignes de données adjacentes et deux lignes de balayage adjacentes, et ayant des premiers transistors à film mince, fournissant des courants à des dispositifs photoémetteurs et des condensateurs, pour maintenir les tensions de données, **caractérisé par** les étapes consistant à :

- (a) précharger le condensateur du circuit à pixel connecté à la ième ligne de balayage avec la première tension de précharge, tandis que le signal de sélection est appliqué à la (i-1)ème ligne de balayage ;
- (b) appliquer des deuxièmes tensions de précharge aux lignes de données, avant que le signal de sélection soit appliqué à la ième ligne de balayage ; et
- (c) stopper l'application de la deuxième tension de décharge lorsque les tensions de données sont appliquées aux lignes de données auxquelles les deuxièmes tensions de précharge ont été appliquées, appliquer des tensions de données correspondantes aux groupes respectifs des lignes de données constitués d'au moins une ligne de données.

20. Procédé selon la revendication 19, dans lequel, à l'étape (b), les tensions de précharge sont appliquées aux lignes de données en même temps.

21. Procédé selon la revendication 19, dans lequel, à l'étape (b), les deuxièmes tensions de précharge sont appliquées aux lignes de données, séquentiellement.

22. Procédé selon la revendication 19, dans lequel, à l'étape (c), l'application des deuxièmes tensions de précharge est stoppée pour toutes les lignes de données, avant que les tensions de données soient appliquées à l'un quelconque de groupes auxquels les deuxièmes tensions de précharge ont été appliquées.

23. Procédé selon la revendication 19, dans lequel, à l'étape (c), avant que des tensions de données soient appliquées séquentiellement à des groupes auxquels les deuxièmes tensions de précharge ont été appliquées, les applications des deuxièmes tensions de précharge aux groupes respectifs sont stoppées séquentiellement.

24. Procédé selon la revendication 19, dans lequel les deuxièmes tensions de précharge ont des valeurs constantes.

25. Procédé selon la revendication 19, dans lequel chacun des circuits à pixel comprend un élément de commutation connecté entre le condensateur et la première tension de précharge, dans lequel, à l'étape (a), les éléments de commutation sont commandés par un signal de sélection appliqué à la (i-1)ème ligne de balayage, pour charger les condensateurs avec les premières tensions de précharge.

26. Procédé selon la revendication 19, dans lequel chacun des circuits à pixel comprend un élément de commutation, connecté entre le condensateur et la première tension de précharge, dans lequel, à l'étape (a), les condensateurs sont chargés avec les premières tensions de précharge par des signaux de remise à l'état initial séparés.

摘要(译)

在显示器中，在将选择信号施加到先前扫描线时，电容器充有第一预充电电压。数据驱动器将多个数据线分成多个组，每个组由至少一个数据线组成，并顺序地将相应的数据电压施加到各个组的数据线。显示器还包括预充电装置，并且这种预充电装置在用于选择扫描线的选择信号施加到连接到像素电路的扫描线上并且停止施加第二预充电电压之前，将第二预充电电压施加到至少一组的数据线。在将相应的数据电压施加到各个组之前。以这种方式，可以解决由于存储在寄生电容器中的先前数据电压引起的电容器的电荷重新分布导致的图像不良的问题。

$$I_{data} = \frac{C}{2} (V_{dd} - V_{TH})^2 = \frac{C}{2} (V_{dd} - V_{TH} - V_{TH})^2 = \frac{C}{2} (V_{dd} - V_{TH})^2 = \frac{C}{2} (V_{dd} - V_{TH})^2$$
