Description

FIELD OF THE INVENTION

[0001] The present invention relates to novel red phosphorescent compounds exhibiting high luminous efficiency and organic electroluminescent devices using the same.

BACKGROUND OF THE INVENTION

[0002] The most important factor to determine luminous efficiency in an OLED (organic light-emitting diode) is the type of electroluminescent material. Though fluorescent materials has been widely used as an electroluminescent material up to the present, development of phosphorescent materials is one of the best methods to improve the luminous efficiency theoretically up to four(4) times, in view of electroluminescent mechanism.

[0003] Up to now, iridium (III) complexes are widely known as phosphorescent material, including (acac)Ir(btp)₂, Ir(ppy)₃ and Firpic, as the red, green and blue one, respectively. In particular, a lot of phosphorescent materials have been recently investigated in Japan and Europe and America.

(acac)Ir(btp)₂Ir(ppy)₃

Firpic

[0004] Among conventional red phosphorescent materials, several materials are reported to have good EL (electroluminescence) properties. However, very rare materials among them have reached the level of commercialization. As the best material, an iridium complex of 1-phenyl isoquinoline may be mentioned, which is known to have excellent EL property and to exhibit color purity of dark red with high luminous efficiency. [See A. Tsuboyama et al., J. Am. Chem. Soc. 2003, 125 (42), 12971-12979.]

1-phenyl isoquinoline

[0005] Moreover, the red materials, having no significant problem of life time, have tendency of easy commercialization if they have good color purity or luminous efficiency. Thus, the above-mentioned iridium complex is a material having very high possibility of commercialization due to its excellent color purity and luminous efficiency.

[0006] However, the iridium complex is still construed only as a material which is applicable to small displays, while higher levels of EL properties than those of known materials are practically required for an OLED panel of medium to large size.

[0007] As a result of intensive efforts of the present inventors to overcome the problems of conventional techniques as described above, they have researched for developing novel red phosphorescent compounds to realize an organic EL device having excellent luminous efficiency and surprisingly improved lifetime. Eventually, the inventors found that luminous efficiency and life property are improved when an iridium complex, which was synthesized by introducing a phenyl derivative at 6-position of quinoline to a primary ligand compound consisting of quinoline and benzene derivative,

is applied as a dopant of an electroluminescent device, and completed the present invention. Thus, the object of the invention is to provide novel red phosphorescent compounds having the skeletal to give more excellent properties as compared to those of conventional red phosphorescent materials. Another object of the invention is to provide novel phosphorescent compounds which are applicable to OLED panels of medium to large size.

SUMMARY OF THE INVENTION

[0008] Thus, the present invention relates to novel red phosphorescent compounds and organic electroluminescent devices employing the same in an electroluminescent layer. Specifically, the red phosphorescent compounds according to the invention are characterized in that they are represented by Chemical Formula (I):

When the reaction was completed, the reaction mixture was cooled to room temperature, and the solid precipitate produced was filtered. Purification via silicagel column chromatography and recrystallization gave Compound (11) (0.8 g, 1.3 mmol, overall yield: 16%) as red crystal.

[0036] According to the same procedure as Preparation Example 1, organic phosphorescent compounds (Compound 1 through Compound 1023) in Table 1 were prepared, of which the ¹H NMR and MS/FAB data are listed in Table 2.

Example 1 - Manufacture of an OLED (1)

[0037] An OLED device was manufactured by using a red phosphorescent compound according to the invention.

[0038] First, a transparent electrode ITO thin film ($15 \Omega/\square$) (2) prepared from a glass for OLED (produced by Samsung Corning) (1) was subjected to ultrasonic washing with trichloroethylene, acetone, ethanol and distilled water, sequentially, and stored in isopronanol before use.

[0039] Then, an ITO substrate was equipped in a substrate folder of a vacuum vapor-deposit device, and 4,4',4"-tris (N,N-(2-naphthyl)-phenylamino)triphenylamine (2-TNATA) was placed in a cell of the vacuum vapor-deposit device, which was then ventilated up to 10^{-6} torr of vacuum in the chamber. Electric current was applied to the cell to evaporate 2-TNATA, thereby providing vapor-deposit of a hole injection layer (3) having 60 nm of thickness on the ITO substrate.

[0040] Then, to another cell of the vacuum vapor-deposit device, charged was N,N'-bis(α -naphthyl)-N,N'-diphenyl-4,4'-diamine (NPB), and electric current was applied to the cell to evaporate NPB, thereby providing vapor-deposit of a hole transportation layer (4) of 20 nm of thickness on the hole injection layer.

[0041] In another cell of said vacuum vapor-deposit device, charged was 4,4'-N,N'-dicarbazole-biphenyl (CBP) as an electroluminescent host material, and a red phosphorescent compound (Compound 1) according to the present invention was charged to still another cell. The two materials were evaporated at different rates to carry out doping to vapor-deposit an electroluminescent layer (5) having 30 nm of thickness on the hole transportation layer. The suitable doping concentration is 4 to 10 mol% on the basis of CBP.

[0042] Then, on the electroluminescent layer, bis(2-methyl-8-quinolinato) (p-phenylphenolato) aluminum (III) (BAIq) was vapor-deposited as a hole blocking layer in a thickness of 10 nm in the same manner for NPB, tris(8-hydroxyquinoline) aluminum (III) (Alq) was vapor-deposited as an electron transportation layer (6) in a thickness of 20 nm, and then lithium quinolate (Liq) was vapor-deposited as an electron injection layer (7) in a thickness of 1 to 2 nm. Thereafter, an Al cathode (8) was vapor-deposited in a thickness of 150 nm by using another vacuum vapor-deposit device to manufacture an OLED.

Example 2 - Manufacture of an OLED (2)

[0043] A hole injection layer and a hole transport layer were formed according to the procedure of Example 1, and an electroluminescent layer was vapor-deposited as follows. In another cell of said vacuum vapor-deposit device, charged was H-4 as an electroluminescent host material, and a red phosphorescent compound (Compound 12) according to the present invention was charged to still another cell. The two materials were evaporated at different rates to carry out doping to vapor-deposit an electroluminescent layer (5) having 30 nm of thickness on the hole transportation layer. The suitable doping concentration is 4 to 10 mol% on the basis of the host. Then, a hole blocking layer, an electron transport layer and an electron injection layer were vapor-deposited according to the same procedure as in Example 1, and then Al cathode (8) was vapor-deposited in a thickness of 150 nm by using another vacuum vapor-deposit device to manufacture an OLED.

Example 3 - Manufacture of an OLED (3)

[0044] A hole injection layer, an hole transport layer and an electroluminescent layer were formed according to the same procedure as in Example 2, and then an electron transport layer and an electron injection layer were vapor-deposited. Thereafter, Al cathode was vapor-deposited in a thickness of 150 nm by using another vacuum vapor-deposit device to manufacture an OLED.

[0045] In order to confirm the performance of the OLED's prepared according to Example 1 through Example 3, the luminous efficiency of the OLED's was measured at 10 mA/cm². Various properties are shown in Tables 3.

[0046] Compound (176) and Compound (188), to which ppy and styrylquinoline were introduced as a subsidiary ligand, respectively, showed high luminous efficiency of 10 cd/A or more. Compound (335), to which F was applied to a ligand as an electron withdrawer, showed the effect of increased efficiency. Compound (787), which employs phenyl(6-phenylpyridin-3-yl)methanone as a subsidiary ligand, showed the highest efficiency among the compounds developed by the present invention.

[0047] With identical device structure, using the host according to the present invention instead of CBP did not provide significant change of efficiency, but the operation voltage was advanced by approximately 0.5 V, and thus enhancement of power consumption could be anticipated. When the host according to the present invention is employed without using a hole blocking layer, the device exhibits comparable or higher luminous efficiency as compared to that using conventional host, and provides decreased power consumption of the OLED due to lowered operation voltage by about 1.3 V ~ 1.7 V. If the invention is applied to mass production of OLEDs, the time for mass production can be also reduced to give great benefit on its commercialization.
