CROSS-REFERENCE TO RELATED APPLICATION

[0001] This application claims priority to and the benefit of Korean Patent Application No. 10-2014-0181615, filed on Dec. 16, 2014, in the Korean Intellectual Property Office, the disclosure of which is incorporated herein in its entirety by reference.

BACKGROUND

[0002] 1. Field

[0003] One or more aspects of embodiments of the present invention relate to an organometallic compound and an organic light-emitting device including the organometallic compound.

[0004] 2. Description of the Related Art

[0005] Organic light-emitting devices (OLEDs) are self-emission devices that have wide viewing angles, high contrast ratios, and short response times. In addition, OLEDs exhibit excellent luminance, low driving voltage, and fast response speed characteristics, and can produce full-color images.

[0006] The organic light-emitting device may include a first electrode disposed on a substrate, and a hole transport region, an emission layer, an electron transport region, and a second electrode sequentially disposed on the first electrode. Holes provided from the first electrode may move toward the emission layer through the hole transport region, and electrons provided from the second electrode may move toward the emission layer through the electron transport region. The holes and the electrons are then recombined in the emission layer to produce excitons. These excitons change from an excited state to a ground state to thereby generate light.

In other words, the organometallic compound represented by Formula 1 has a substituent selected from a C_5 - C_{10} cycloalkyl group; and a C_5 - C_{10} cycloalkyl group substituted with at least one C_1 - C_{10} alkyl group at a position of at least one of R_1 and R_2 . The C_5 - C_{10} cycloalkyl group and the C_5 - C_{10} cycloalkyl group substituted with at least one C_1 - C_{10} alkyl group are bulky groups having a relatively large number of carbon atoms, and thus may effectively provide electrons to the organometallic compound represented by Formula 1. Accordingly, an organic light-emitting device including the organometallic compound represented by Formula 1 may emit green light with high purity and high efficiency.

[0076] The organometallic compound represented by Formula 1 may be synthesized using one or more suitable organic synthesis methods commonly known to those of skill in the art. [0077] At least one of the organometallic compounds represented by Formula 1 may be used (utilized) between a pair of electrodes of an organic light-emitting device. For example, the organometallic compound may be included in an emission layer. Here, the organometallic compound included in the emission layer of the organic light-emitting device serves as a phosphorescent dopant, and the emission layer may further include a host.

[0078] According to one or more embodiments of the present invention, an organic light-emitting device includes a first electrode; a second electrode facing the first electrode; and an organic layer between the first electrode and the second electrode, wherein the organic layer includes at least one organometallic compound represented by Formula 1.

[0079] As used herein, the phrase “organic layer includes at least one organometallic compound” may be construed as “organic layer may include one organometallic compound represented by Formula 1 or two or more different organometallic compounds represented by Formula 1”.

[0080] In some embodiments, an organic layer of an organic light-emitting device may include only Compound 1 as the organometallic compound. In this regard, Compound 1 may be included in an emission layer of the organic light-emitting device. In other embodiments, the organic layer may include Compound 1 and Compound 17 as the organometallic compound. The emission layer may include the organometallic compound represented by Formula 1.

[0082] In some embodiments, the emission layer may include at least one organometallic compound represented by Formula 1. The emission layer including at least one organometallic compound represented by Formula 1 may further include a host. The organometallic compound may serve as a dopant in the emission layer, and the amount of the organometallic compound may be less than the amount of the host.

[0083] As used herein, the term “organic layer” refers to a single layer and/or a plurality of layers between the first electrode and the second electrode in an organic light-emitting device. A material included in the “organic layer” is not limited to an organic material.

[0084] FIG. 1 is a schematic view of an organic light-emitting device 10 according to one or more embodiments of the present invention. The organic light-emitting device 10 includes a first electrode 110, an organic layer 150, and a second electrode 190.

[0085] Hereinafter, a structure and a method of manufacturing an organic light-emitting device according to one or more embodiments will be described with reference to FIG. 1.

[0086] Referring to FIG. 1, a substrate may be additionally disposed under the first electrode 110 or on the second electrode 190. The substrate may be a glass substrate or transparent plastic substrate, each with excellent mechanical strength, thermal stability, transparency, surface smoothness, ease of handling, and water resistance.

[0087] The first electrode 110 may be formed by depositing or sputtering a material for forming the first electrode 110 on the substrate. When the first electrode 110 is an anode, the material for the first electrode 110 may be selected from materials with a high work function so as to facilitate hole injection. The first electrode 110 may be a reflective electrode, a semi-transmissive electrode, or a transmissive electrode. The material for the first electrode 110 may be a transparent and highly conductive material, and non-limiting examples of such material include indium tin oxide (ITO), indium zinc oxide (IZO), tin oxide (SnO₂), and zinc oxide (ZnO). When the first electrode 110 is a semi-transmissive electrode or a reflective electrode, as a material for forming the first electrode 110, at least one selected from magnesium (Mg), aluminum (Al), aluminum-lithium (Al—Li), calcium (Ca), magnesium-indium (Mg—In), and magnesium-silver (Mg—Ag) may be used (utilized).

[0089] The organic layer 150 is positioned on the first electrode 110. The organic layer 150 may include an emission layer.

[0090] The organic layer 150 may further include a hole transport region between the first electrode 110 and the emission layer, and an electron transport region between the emission layer and the second electrode 190.

[0091] The hole transport region may include at least one selected from a hole injection layer (HIL), a hole transport layer (HTL), a buffer layer, and an electron blocking layer (EBL), and the electron transport region may include at least one selected from a hole blocking layer (HBL), an electron transport layer (ETL), and an electron injection layer (EIL), but embodiments of the present invention are not limited thereto.

[0092] The hole transport region may have a single-layered structure formed of a single material, a single-layered structure formed of a plurality of different materials, or a multi-layered structure having a plurality of layers formed of a plurality of different materials.

[0093] For example, the hole transport region may have a single-layered structure formed of a plurality of different materials, or a structure of hole injection layer/hole transport layer, a structure of hole injection layer/hole transport layer/buffer layer, a structure of hole injection layer/buffer layer, a structure of hole transport layer/buffer layer, or a structure of hole injection layer/hole transport layer/electron blocking layer, wherein the layers of each structure are sequentially stacked from the first electrode 110 in the stated order, but embodiments of the present invention are not limited thereto.

[0118] A thickness of the hole transport region may be in a range of about 100 Å to about 10,000 Å, for example, about 100 Å to about 1000 Å. When the hole transport region includes a hole injection layer and a hole transport layer, a thickness of the hole injection layer may be in a range of about 100 Å to about 10,000 Å, for example, about 100 Å to about 9,950 Å, or about 100 Å to about 1000 Å, and a thickness of the hole transport layer may be in a range of about 50 Å to about 2000 Å, for example, about 100 Å to about 1500 Å. When the thicknesses of the hole transport region, the hole injection layer, and the hole transport layer are within any of these ranges, good hole transport characteristics may be obtained without a substantial increase in driving voltage.

[0119] The hole transport region may further include, in addition to the materials mentioned above, a charge-generating material to improve conductive properties. The charge-generating material may be homogeneously or non-homogeneously dispersed throughout the hole transport region.

[0120] The charge-generating material may be, for example, a p-dopant. The p-dopant may be one selected from a quinone derivative, a metal oxide, and a cyano group-containing compound, but embodiments of the present invention are not limited thereto. Non-limiting examples of the p-dopant include quinone derivatives such as tetracyanoquinonodimethane (TCNQ) and/or 2,3,5,6-tetrafluoro-tetracyano-1,4-benzoquinonodimethane (F4-TCNQ); metal oxides such as a tungsten oxide and/or a molybdenum oxide; and Compound HT-D1:

Compound HT-D1

[0121] The hole transport region may further include, in addition to the hole injection layer and the hole transport layer, at least one selected from a buffer layer and an electron blocking layer. Since the buffer layer may compensate for an optical resonance distance according to a wavelength of light emitted from the emission layer, the light-emission efficiency of the resulting organic light-emitting device may be improved. As a material included in the buffer layer, materials that are included in the hole transport region may be used (utilized). In some embodiments, the electron blocking layer prevents or substantially reduces or blocks the injection of electrons from the electron transport region.

[0122] An emission layer may be formed on the first electrode 110 or the hole transport region by using one or more suitable methods, such as vacuum deposition, spin coating, casting, an LB method, inkjet printing, laser printing, and/or LITI. When the emission layer is formed by vacuum deposition and/or spin coating, deposition and coating conditions for the emission layer may be similar to the deposition and coating conditions for the hole injection layer.

[0123] When the organic light-emitting device 10 is a full-color organic light-emitting device, the emission layer may be patterned into a red emission layer, a green emission layer, or a blue emission layer, according to a sub-pixel. Alternatively, the emission layer may have a stacked structure of a red emission layer, a green emission layer, and a blue emission layer, or may include a red-light emission material, a green-light emission material, and a blue-light emission material, which are mixed with each other in a single layer, to emit white light.

[0124] The emission layer may include a host and a dopant. The dopant included in the emission layer may include the organometallic compound represented by Formula 1.

[0179] In the emission layer, a concentration of the organometallic compound represented by Formula 1 may be in a range of about 1 wt % to about 30 wt % based on 100 wt % of the emission layer. When the concentration of the organometallic compound is within this range, an organic light-emitting device may effectively emit light without a substantial excitation quenching.

[0180] A thickness of the emission layer may be in a range of about 100 Å to about 1000 Å, for example, about 200 Å to about 600 Å. When the thickness of the emission layer is within this range, good light-emission characteristics may be obtained without a substantial increase in driving voltage.

[0181] Then, an electron transport region may be positioned on the emission layer.

[0182] The electron transport region may include at least one selected from a hole blocking layer, an electron transport layer, and an electron injection layer, but embodiments of the present invention are not limited thereto.

[0183] For example, the electron transport region may have a structure of electron transport layer/electron injection layer or a structure of hole blocking layer/electron transport layer/electron injection layer, wherein the layers of each structure are sequentially stacked from the emission layer in the stated order, but embodiments of the present invention are not limited thereto.

[0184] In some embodiments, the organic layer 150 of the organic light-emitting device may include an electron transport region between the emission layer and the second electrode 190.

[0185] When the electron transport region includes a hole blocking layer, the hole blocking layer may be formed on the emission layer by using one or more suitable methods, such as vacuum deposition, spin coating, casting, an LB method, inkjet printing, laser printing, and/or LITI. When the hole blocking layer is formed by vacuum deposition and/or spin coating, deposition and coating conditions for the hole blocking layer may be similar to the deposition and coating conditions for the hole injection layer.

[0186] The hole blocking layer may include, for example, at least one selected from BCP and Bphen, but embodiments of the present invention are not limited thereto:

BCP

Bphen

[0187] A thickness of the hole blocking layer may be in a range of about 20 Å to about 1000 Å, for example, about 30 Å to about 300 Å. When the thickness of the hole blocking layer is within this range, good hole blocking characteristics may be obtained without a substantial increase in driving voltage.

[0188] The electron transport layer may be formed on the emission layer or the hole blocking layer by using one or more suitable methods, such as vacuum deposition, spin coating, casting, an LB method, inkjet printing, laser printing, and/or LITI. When the electron transport layer is formed by using vacuum deposition and/or spin coating, vacuum deposition and coating conditions for the electron transport layer may be similar to the vacuum deposition and coating conditions for the hole injection layer.

EXAMPLE

Synthesis Example 1

Synthesis of Compound 1

[0240]

Synthesis of Intermediate 1-1
(2-(4-methylphenyl)-4-aminopyridine)

[0241] 25 g (183.89 mmol) of 4-methylphenyl boronic acid, 19.70 g (153.24 mmol) of 2-chloro-4-aminopyridine, 80 mL of a 2M K_2CO_3 aqueous solution, and 350 mL of toluene were added to a 1000 mL 3-neck round bottom flask that was first dried using a torch. The reaction mixture was degassed for 30 minutes and heated to a temperature of 60° C. Then, 8.87 g (3 mol %) of $Pd(PPh_3)_4$ was added thereto, and the resulting mixture was stirred at 90° C. under nitrogen airflow for 15 hours. The obtained reaction mixture was cooled to room temperature and washed with an excessive amount of water. Then, an organic layer was extracted therefrom using 2M hydrochloric acid and ethyl acetate, and moisture was removed therefrom with anhydrous $MgSO_4$. The resultant thus obtained was filtered using a low-pressure filtering device and separated through column chromatography using dichloromethane, as a solvent, and thus Intermediate 1-1 (2-(4-methylphenyl)-4-aminopyridine) (yield: 76%) was obtained.

[0242] 1H -NMR (300 MHz, $CDCl_3$, ppm): δ 8.32-8.30 (d, 1H), 7.84-7.81 (d, 2H), 7.25 (s, 1H), 6.95-6.94 (d, 2H), 6.350-6.47 (m, 1H), 4.19 (s, 2H), 2.41 (s, 3H)

Synthesis of Intermediate 1-2
(2-(4-methylphenyl)-4-bromopyridine)

[0243] 21.53 g (116.89 mmol) of Intermediate 1-1, 450 mL of HBr, 400 mL of distilled water, and (0.44 g, 3 mol %) of CuBr were added to a 1000 mL 3-neck round bottom flask that was first dried using a torch. The reaction mixture was stirred at 60° C. under nitrogen airflow for 30 minutes. Then, 31.71 g (459.72 mmol) of 5N $NaNO_2$ was added thereto, and the

resulting mixture was stirred at 60° C. under nitrogen airflow for 1 hour. The obtained reaction mixture was cooled to room temperature and titrated to pH 10 using 50% NaOH. Then, the resultant was extracted therefrom using water and dichloromethane, and moisture was removed therefrom with anhydrous $MgSO_4$. The resultant thus obtained was filtered using a low-pressure filtering device and separated through column chromatography using n-hexane/dichloromethane (at a v/v ratio of 1:1), as a solvent, and thus Intermediate 1-2 (2-(4-methylphenyl)-4-bromopyridine) (yield: 46%) was obtained.

[0244] 1H -NMR (300 MHz, $CDCl_3$, ppm): δ 8.53-8.49 (d, 1H), 7.90-7.89 (d, 2H), 7.87 (s, 1H), 7.40-7.39 (m, 1H), 7.32-7.29 (d, 2H), 2.43 (s, 3H)

Synthesis of Intermediate 1-3
(2-(4-methylphenyl)-4-cyclohexylpyridine)

[0245] 8.38 g (33.77 mmol) of Intermediate 1-2 and 200 mL of THF were added to a 50 mL 3-neck round bottom flask that was first dried using a torch. The reaction mixture was degassed for 30 minutes and stirred at 130° C. under nitrogen airflow for 1 hour. After cooling the resulting reaction mixture to a temperature of -25° C. using liquid nitrogen, 0.18 g (1 mol %) of $Ni(dppp)_2Cl_2$ was injected thereto, and the mixture was stirred for 30 minutes. Then, 20.26 mL (50.66 mmol) of cyclohexylmagnesium bromide was injected thereto, and the obtained mixture was stirred for 4 hours and then heated to room temperature. The resultant was extracted therefrom using 2M hydrochloric acid and ether, and moisture was removed therefrom with anhydrous $MgSO_4$. The resultant thus obtained was filtered using a low-pressure filtering device and separated through column chromatography using n-hexane/ethyl acetate (at a v/v ratio of 20:1), as a solvent, and thus Intermediate 1-3 (2-(4-methylphenyl)-4-cyclohexylpyridine) (yield: 58%) was obtained.

Evaluation Example 1

Evaluation of Light-Emitting Characteristics of
Compound 1 and Compound 17

[0253] Light-emitting characteristics of each of Compounds 1 and 17 were evaluated by analyzing a UV absorption spectrum and a PL spectrum of Compounds 1 and 17. First, Compound 1 was diluted in CH₂Cl₂ at a concentration of 10⁻⁵ M to obtain a UV absorption spectrum of Compound 1 by using a Shimadzu UV-350 Spectrometer. This process was then repeated for Compound 17 and Ir(ppy)₃. In addition, Compound 1 was diluted in CH₂Cl₂ at a concentration of 10⁻⁵ M to obtain a PL spectrum of Compound 1 by using an ISS PC1 Spectrofluorometer with a xenon lamp. This process was then repeated for Compound 17 and Ir(ppy)₃. The results are shown in Table 1, and the UV absorption spectrum and the PL spectrum of Compound 1 and Ir(ppy)₃ are shown in FIG. 2.

TABLE 1

	Peak position of UV absorption spectrum (nm)	Maximum emission wavelength in PL spectrum (nm)	PL color coordinate
Compound 1	289, 377	466	(0.217, 0.611)
Compound 17	247, 288, 380	508	(0.245, 0.634)
Ir(ppy) ₃	244, 283, 380	513	(0.266, 0.633)

Compound 1

Compound 17

Ir(ppy)₃

[0254] Referring to Table 1 and FIG. 2, emission peaks of Compound 1 and Compound 17 have maximum emission wavelengths (λ_{max}) that are smaller than that of an emission peak of Ir(ppy)₃, and accordingly, Compound 1 and Compound 17 can emit green light with high color purity.

Example 1

[0255] A indium tin oxide (ITO) glass substrate (available from Corning) having an ITO layer deposited thereon at a thickness of 15 Ω/cm^2 (1200 Å) was cut to a size of 50 mm $\times$ 50 mm $\times$ 0.7 mm, sonicated in isopropyl alcohol and pure water for 5 minutes each, and then cleaned with UV and ozone for 30 minutes. The obtained ITO glass substrate was then mounted on a vacuum depositor.

[0256] 4,4'-Bis[N-phenyl-N-(9-phenylcarbazol-3-yl)amino]-1,1'-biphenyl (NPB) was deposited on the ITO glass substrate to form a hole injection layer having a thickness of 400 Å, TCTA was deposited on the hole injection layer to form a hole transport layer having a thickness of 100 Å, and then CBP (a host) and Compound 1 (a dopant) were co-deposited at a weight ratio of 95:5 on the hole transport layer to form an emission layer having a thickness of 300 Å. Bphen was deposited on the emission layer to form an electron transport layer having a thickness of 500 Å, LiF was deposited on the electron transport layer to form an electron injection layer having a thickness of 10 Å, and Al was deposited on the electrode injection layer to form a cathode having a thickness of 1100 Å, thereby completing the manufacture of an organic light-emitting device.
