(57) **ABSTRACT**

A signal processor generates basis functions and identifies at least one basis function component of a sensor signal in order to calculate a physiological measurement. The signal processor is advantageously applied to pulse oximetry so as to directly calculate oxygen saturation and so as to calculate a robust oxygen saturation measurement. In particular, a signal component transform may be calculated within a window around a derived pulse rate estimate. A signal component transform may also utilize sinusoidal basis functions, and an optimization of a signal component transform may occur at a particular frequency or a set of frequencies. A sinusoidal waveform or waveforms at that frequency or set of frequencies is generated to select associated red and infrared components of the sensor signal, and an oxygen saturation is calculated from a magnitude ratio of these components.

SIGNAL COMPONENT PROCESSOR

CROSS-REFERENCE TO RELATED APPLICATIONS

This application relates to and claims the benefit of prior provisional application No. 60/302,438 entitled "Signal Component Processor," filed Jun. 29, 2001 and incorporated by reference herein.

BACKGROUND OF THE INVENTION

Early detection of low blood oxygen is critical in the medical field, for example in critical care and surgical applications, because an insufficient supply of oxygen can result in brain damage and death in a matter of minutes. Pulse oximetry is a widely accepted noninvasive procedure for measuring the oxygen saturation level of arterial blood, an indicator of oxygen supply. A pulse oximeter typically provides a numerical readout of the patient's oxygen saturation and pulse rate. A pulse oximetry system consists of a sensor attached to a patient, a monitor, and a cable connecting the sensor and monitor. Conventionally, a pulse oximetry sensor has both red (RD) and infrared (IR) light-emitting diode (LED) emitters and a photodiode detector. The pulse oximeter measurements are based upon the absorption by arterial blood of the two wavelengths emitted by the sensor. The pulse oximeter alternately activates the RD and IR sensor emitters and reads the resulting RD and IR sensor signals, i.e. the current generated by the photodiode in proportion to the detected RD and IR light intensity, in order to derive an arterial oxygen saturation value, as is well-known in the art. A pulse oximeter contains circuitry for controlling the sensor, processing the sensor signals and displaying the patient's oxygen saturation and pulse rate.

SUMMARY OF THE INVENTION

FIG. 1A illustrates a plethysmograph waveform **110**, which is a display of blood volume, shown along the ordinate **101**, over time, shown along the abscissa **102**. The shape of the plethysmograph waveform **110** is a function of heart stroke volume, pressure gradient, arterial elasticity and peripheral resistance. Ideally, the waveform **110** displays a short, steep inflow phase **111** during ventricular systole followed by a typically three to four times longer outflow phase **112** during diastole. A dicrotic notch **116** is generally attributed to closure of the aortic valve at the end of ventricular systole.

FIG. 1B illustrates a corresponding RD or IR sensor signal $s(t)$ **130**, such as described above. The typical plethysmograph waveform **110** (FIG. 1A), being a function of blood volume, also provides a light absorption profile. A pulse oximeter, however, does not directly detect light absorption and, hence, does not directly measure the plethysmograph waveform **110**. However, IR or RD sensor signals are 180° out-of-phase versions of the waveform **110**. That is, peak detected intensity **134** occurs at minimum absorption **114** and minimum detected intensity **138** occurs at maximum absorption **118**.

FIG. 1C illustrates the corresponding spectrum of $s(t)$, which is a display of signal spectral magnitude $|S(\omega)|$, shown along the ordinate **105**, versus frequency, shown along the abscissa **106**. The plethysmograph spectrum is depicted under both high signal quality **150** and low signal quality **160** conditions. Low signal quality can result when a pulse oximeter sensor signal is distorted by motion-artifact and noise. Signal processing technologies such as described in

U.S. Pat. No. 5,632,272, assigned to the assignee of the present invention and incorporated by reference herein, allow pulse oximetry to function through patient motion and other low signal quality conditions.

Ideally, plethysmograph energy is concentrated at the pulse rate frequency **172** and associated harmonics **174**, **176**. Accordingly, motion-artifact and noise may be reduced and pulse oximetry measurements improved by filtering out sensor signal frequencies that are not related to the pulse rate. Under low signal quality conditions, however, the frequency spectrum is corrupted and the pulse rate fundamental **152** and harmonics **154**, **156** can be obscured or masked, resulting in errors in the computed pulse rate. In addition, a pulse rate, physiologically, is dynamic, potentially varying significantly between different measurement periods. Hence, maximum plethysmograph energy may not correspond to the computed pulse rate except under high signal quality conditions and stable pulse rates. Further, an oxygen saturation value calculated from an optical density ratio, such as a normalized red over infrared ratio, at the pulse rate frequency can be sensitive to computed pulse rate errors. In order to increase the robustness of oxygen saturation measurements, therefore, it is desirable to improve pulse rate based measurements by identifying sensor signal components that correspond to an optimization, such as maximum signal energy.

One aspect of a signal component processor comprises a physiological signal, a basis function index determined from the signal, a basis function waveform generated according to the index, a component derived from the sensor signal and the waveform, and a physiological measurement responsive to the component. In one embodiment, the component is responsive to the inner product of the sensor signal and the waveform. In another embodiment, the index is a frequency and the waveform is a sinusoid at the frequency. In that embodiment, the signal processor may further comprise a pulse rate estimate derived from the signal wherein the frequency is selected from a window including the pulse rate estimate. The physiological measurement may be an oxygen saturation value responsive to a magnitude of the component.

Another aspect of a signal component processor comprises a signal input, a basis function indicator derived from the signal input, a plurality of basis functions generated according to the indicator, a plurality of characteristics of the signal input corresponding to the basis functions and an optimization of the characteristics so as to identify at least one of said basis functions. In one embodiment, the indicator is a pulse rate estimate and the processor further comprises a window configured to include the pulse rate estimate, and a plurality of frequencies selected from within the window. In another embodiment, the characteristic comprises a plurality of signal remainders corresponding to the basis functions and a plurality of magnitudes of the signal remainders. In that embodiment, the optimization comprises a minima of the magnitudes. In a further embodiment, the characteristic comprises a plurality of components corresponding to the basis functions and a plurality of magnitudes of the components. In this embodiment, the optimization comprises a maxima of the magnitudes.

An aspect of a signal component processing method comprises the steps of receiving a sensor signal, calculating an estimated pulse rate, determining an optimization of the sensor signal proximate the estimated pulse rate, defining a frequency corresponding to the optimization, and outputting a physiological measurement responsive to a component of the sensor signal at the frequency. In one embodiment the

determining step comprises the substeps of transforming the sensor signal to a frequency spectrum encompassing the estimated pulse rate and detecting an extrema of the spectrum indicative of the frequency. The transforming step may comprise the substeps of defining a window including the estimated pulse rate, defining a plurality of selected frequencies within the window, canceling the selected frequencies, individually, from the sensor signal to generate a plurality of remainder signals and calculating a plurality of magnitudes of the remainder signals. The detecting step may comprise the substep of locating a minima of the magnitudes.

In another embodiment, the outputting step comprises the substeps of inputting a red (RD) portion and an infrared (IR) portion of the sensor signal, deriving a RD component of the RD portion and an IR component of the IR portion corresponding to the frequency and computing an oxygen saturation based upon a magnitude ratio of the RD component and the IR component. The deriving step may comprise the substeps of generating a sinusoidal waveform at the frequency and selecting the RD component and the IR component utilizing the waveform. The selecting step may comprise the substep of calculating the inner product between the waveform and the RD portion and the inner product between the waveform and the IR portion. The selecting step may comprise the substeps of canceling the waveform from the RD portion and the IR portion, leaving a RD remainder and an IR remainder, and subtracting the RD remainder from the RD portion and the IR remainder from the IR portion.

A further aspect of a signal component processor comprises a first calculator means for deriving an optimization frequency from a pulse rate estimate input and a sensor signal, and a second calculator means for deriving a physiological measurement responsive to a sensor signal component at the frequency. In one embodiment, the first calculator means comprises a signal component transform means for determining a plurality of signal values corresponding to a plurality of selected frequencies within a window including the pulse rate estimate, and a detection means for determining a particular one of the selected frequencies corresponding to an optimization of the sensor signal. The second calculator means may comprise a waveform means for generating a sinusoidal signal at the frequency, a frequency selection means for determining a component of the sensor signal from the sinusoidal signal and a calculator means for deriving a ratio responsive to the component.

BRIEF DESCRIPTION OF THE DRAWINGS

FIGS. 1A–C are graphical representations of a pulse oximetry sensor signal;

FIG. 1A is a typical plethysmograph illustrating blood volume versus time;

FIG. 1B is a pulse oximetry sensor signal illustrating detected light intensity versus time;

FIG. 1C is a pulse oximetry sensor signal spectrum illustrating both high signal quality and low signal quality conditions;

FIGS. 2–3 are magnitude versus frequency graphs for a pulse oximetry sensor signal illustrating an example of signal component processing;

FIG. 2 illustrates a frequency window around an estimated pulse rate; and

FIG. 3 illustrates an associated signal component transform;

FIGS. 4–7 are functional block diagrams of one embodiment of a signal component processor;

FIG. 4 is a top-level functional block diagram of a signal component processor;

FIG. 5 is a functional block diagram of a frequency calculator;

FIG. 6 is a functional block diagram of a saturation calculator; and

FIG. 7 is a functional block diagram of one embodiment of a frequency selection;

FIGS. 8A–B are flowcharts of an iterative embodiment of a frequency calculator; and

FIGS. 9–11 are functional block diagrams of another embodiment of a signal component processor;

FIG. 9 is a top-level functional block diagram of a signal component processor;

FIG. 10 is a functional block diagram of an index calculator; and

FIG. 11 is a functional block diagram of a measurement calculator.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

FIGS. 2 and 3 provide graphical illustration examples of signal component processing. Advantageously, signal component processing provides a direct method for the calculation of saturation based on pulse rate. For example, it is not necessary to compute a frequency transform, such as an FFT, which derives an entire frequency spectrum. Rather, signal component processing singles out specific signal components, as described in more detail below. Further, signal component processing advantageously provides a method of refinement for the calculation of saturation based on pulse rate.

FIG. 2 illustrates high and low signal quality sensor signal spectrums **150**, **160** as described with respect to FIG. 1C, above. A frequency window **220** is created, including a pulse rate estimate PR **210**. A pulse rate estimate can be calculated as disclosed in U.S. Pat. No. 6,002,952, entitled “Signal Processing Apparatus and Method,” assigned to the assignee of the present invention and incorporated by reference herein. A search is conducted within this window **220** for a component frequency f_0 at an optimization. In particular, selected frequencies **230**, which include PR, are defined within the window **220**. The components of a signals(t) at each of these frequencies **230** are then examined for an optimization indicative of an extrema of energy, power or other signal characteristic. In an alternative embodiment, the components of the signals(t) are examined for an optimization over a continuous range of frequencies within the window **220**.

FIG. 3 illustrates an expanded portion of the graph described with respect to FIG. 2, above. Superimposed on the high signal quality **150** and low signal quality **160** spectrums is a signal component transform **310**. In one embodiment, a signal component transform **310** is indicative of sensor signal energy and is calculated at selected signal frequencies **230** within the window **220**. A signal component transform **310** has an extrema **320** that indicates, in this embodiment, energy optimization at a particular one **330** of the selected frequencies **230**. The extrema **320** can be, for example, a maxima, minima or inflection point. In the embodiment illustrated, each point of the transform **310** is the magnitude of the signal remaining after canceling a sensor signal component at one of the selected frequencies. The extrema **320** is a minima, which indicates that canceling the corresponding frequency **330** removes the most signal

energy. In an alternative embodiment, not illustrated, the transform **310** is calculated as the magnitude of signal components at each of the selected frequencies **230**. In that embodiment, the extrema is a maxima, which indicates the largest energy signal at the corresponding frequency. The result of a signal component transform **310** is identification of a frequency f_0 **330** determined from the frequency of a signal component transform extrema **320**. Frequency f_0 **330** is then used to calculate an oxygen saturation. A signal component transform and corresponding oxygen saturation calculations are described in additional detail with respect to FIGS. 4–8, below. Although signal component processing is described above with respect to identifying a particular frequency within a window including a pulse rate estimate PR, a similar procedure could be performed on 2PR, 3PR etc. resulting in the identification of multiple frequencies f_{01} , f_{02} , etc., which could be used for the calculation of oxygen saturation as well.

Advantageously, a signal component transform **310** is calculated over any set of selected frequencies, unrestricted by the number or spacing of these frequencies. In this manner, a signal component transform **310** differs from a FFT or other standard frequency transforms. For example, a FFT is limited to N evenly-distributed frequencies spaced at a resolution of f_s/N , where N is the number of signal samples and f_s is the sampling frequency. That is, for a FFT, a relatively high sampling rate or a relatively large record length or both are needed to achieve a relatively high resolution in frequency. Signal component processing, as described herein, is not so limited. Further, a signal component transform **310** is advantageously calculated only over a range of frequencies of interest. A FFT or similar frequency transformation may be computationally more burdensome than signal component processing, in part because such a transform is computed over all frequencies within a range determined by the sampling frequency, f_s .

FIGS. 4–7 illustrate one embodiment of a signal component processor. FIG. 4 is a top-level functional block diagram of a signal component processor **400**. The signal component processor **400** has a frequency calculator **410** and a saturation calculator **460**. The frequency calculator **410** has an IR signal input **402**, a pulse rate estimate signal PR input **408** and a component frequency f_0 output **412**. The frequency calculator **410** performs a signal component transform based upon the PR input **408** and determines the f_0 output **412**, as described with respect to FIGS. 2–3, above. The frequency calculator **410** is described in further detail with respect to FIG. 5, below.

In an alternative embodiment, the frequency calculator **410** determines f_0 **412** based upon a RD signal input substituted for, or in addition to, the IR signal input **402**. Similarly, one of ordinary skill in the art will recognize that f_0 can be determined by the frequency calculator **410** based upon one or more inputs responsive to a variety of sensor wavelengths.

The saturation calculator **460** has an IR signal input **402**, a RD signal input **404**, a component frequency f_0 input **412** and an oxygen saturation output, SAT_{f_0} **462**. The saturation calculator **460** determines values of the IR signal input **402** and the RD signal input **404** at the component frequency f_0 **412** and computes a ratio of those values to determine SAT_{f_0} **462**, as described with respect to FIG. 6, below. The IR signal input **402** and RD signal input **404** can be expressed as:

$$IR = \begin{bmatrix} IR_0 \\ \vdots \\ IR_{N-1} \end{bmatrix}; RD = \begin{bmatrix} RD_0 \\ \vdots \\ RD_{N-1} \end{bmatrix} \quad (1)$$

where N is the number of samples of each signal input.

FIG. 5 shows one embodiment of the frequency calculator **410**. In this particular embodiment, the frequency calculator functions are window generation **520**, frequency cancellation **540**, magnitude calculation **560** and minima determination **580**. Window generation **520**, frequency cancellation **540** and magnitude calculation **560** combine to create a signal component transform **310** (FIG. 3), as described with respect to FIG. 3, above. Minima determination **580** locates the signal component transform extrema **320** (FIG. 3), which identifies f_0 **412**, also described with respect to FIG. 3, above.

As shown in FIG. 5, window generation **520** has a PR input **408** and defines a window **220** (FIG. 3) about PR **210** (FIG. 3) including a set of selected frequencies **230** (FIG. 3)

$$\{f_m; m = 0, \dots, M-1\}; f = \begin{bmatrix} f_0 \\ \vdots \\ f_{M-1} \end{bmatrix} \quad (2)$$

where M is the number of selected frequencies **230** (FIG. 3) within the window **220** (FIG. 3). Window generation **520** has a sinusoidal output X_f, Y_f **522**, which is a set of sinusoidal waveforms $x_{n,f}, y_{n,f}$ each corresponding to one of the set of selected frequencies **230** (FIG. 3). Specifically

$$X_f = \begin{bmatrix} x_{0,f} \\ \vdots \\ x_{N-1,f} \end{bmatrix}; Y_f = \begin{bmatrix} y_{0,f} \\ \vdots \\ y_{N-1,f} \end{bmatrix} \quad (3a)$$

$$x_{n,f} = \sin(2\pi f n); y_{n,f} = \cos(2\pi f n) \quad (3b)$$

Also shown in FIG. 5, the frequency cancellation **540** has IR **402** and X_f, Y_f **522** inputs and a remainder output R_f **542**, which is a set of remainder signals $r_{n,f}$ each corresponding to one of the sinusoidal waveforms $x_{n,f}, y_{n,f}$. For each selected frequency f **230** (FIG. 3), frequency cancellation **540** cancels that frequency component from the input signal IR **402** to generate a remainder signal $r_{n,f}$. In particular, frequency cancellation **540** generates a remainder R_f **542**

$$R_f = \begin{bmatrix} r_{0,f} \\ \vdots \\ r_{N-1,f} \end{bmatrix} \quad (4a)$$

$$R_f = IR - \frac{IR \cdot X_f}{|X_f|^2} X_f - \frac{IR \cdot Y_f}{|Y_f|^2} Y_f \quad (4b)$$

Additionally, as shown in FIG. 5, the magnitude calculation **560** has a remainder input R_f **542** and generates a magnitude output W_f **562**, where

$$W_f = |R_f| = \sqrt{\sum_{n=0}^{N-1} r_{n,f}^2} \quad (5)$$

Further shown in FIG. 5, the minima determination 580 has the magnitude values W_f 562 as inputs and generates a component frequency f_0 output. Frequency f_0 is the particular frequency associated with the minimum magnitude value

$$W_{f_0} = \min\{W_f\} \quad (6)$$

FIG. 6 shows that the saturation calculator 460 functions are sinusoid generation 610, frequency selection 620, 640 and ratio calculation 670. Sinusoid generation has a component frequency f_0 input 208 and a sinusoidal waveform X_{f_0} , Y_{f_0} output 612, which has a frequency of f_0 . Frequency selection 620, 640 has a sensor signal input, which is either an IR signal 202 or a RD signal 204 and a sinusoid waveform X_{f_0} , Y_{f_0} input 612. Frequency selection 620, 640 provides magnitude outputs z_{IR,f_0} 622 and z_{RD,f_0} 642 which are the frequency components of the IR 202 and RD 204 sensor signals at the f_0 frequency. Specifically, from equation 3(a)

$$X_{f_0} = \begin{bmatrix} x_{0,f_0} \\ \vdots \\ x_{N-1,f_0} \end{bmatrix}; Y_{f_0} = \begin{bmatrix} y_{0,f_0} \\ \vdots \\ y_{N-1,f_0} \end{bmatrix} \quad (7)$$

Then, referring to equation 1

$$z_{IR,f_0} = \left| \frac{IR \cdot X_{f_0}}{|X_{f_0}|^2} X_{f_0} + \frac{IR \cdot Y_{f_0}}{|Y_{f_0}|^2} Y_{f_0} \right| = \sqrt{\frac{(IR \cdot X_{f_0})^2}{|X_{f_0}|^2} + \frac{(IR \cdot Y_{f_0})^2}{|Y_{f_0}|^2}} \quad (8a)$$

$$z_{RD,f_0} = \left| \frac{RD \cdot X_{f_0}}{|X_{f_0}|^2} X_{f_0} + \frac{RD \cdot Y_{f_0}}{|Y_{f_0}|^2} Y_{f_0} \right| = \sqrt{\frac{(RD \cdot X_{f_0})^2}{|X_{f_0}|^2} + \frac{(RD \cdot Y_{f_0})^2}{|Y_{f_0}|^2}} \quad (8b)$$

For simplicity of illustration, EQS. 8a–b assume that the cross-product of X_{f_0} and Y_{f_0} is zero, although generally this is not the case. The ratio calculation and mapping 670 has z_{IR,f_0} 622 and z_{RD,f_0} 642 as inputs and provides SAT $_{f_0}$ 262 as an output. That is

$$SAT_{f_0} = g\{z_{RD,f_0}/z_{IR,f_0}\} \quad (9)$$

where g is a mapping of the red-over-IR ratio to oxygen saturation, which may be an empirically derived lookup table, for example.

FIG. 7 illustrates an alternative embodiment of frequency selection 620 (FIG. 6), as described above. In this embodiment, frequency cancellation 540 and magnitude calculation 560, as described with respect to FIG. 5, can also be used, advantageously, to perform frequency selection. Specifically, frequency cancellation 540 has IR 202 and X_{f_0} , Y_{f_0} 612 as inputs and generates a remainder signal R_{f_0} 712 as an output, where

$$R_{f_0} = IR - \frac{IR \cdot X_{f_0}}{|X_{f_0}|^2} X_{f_0} - \frac{IR \cdot Y_{f_0}}{|Y_{f_0}|^2} Y_{f_0} \quad (10)$$

The remainder R_{f_0} 712 is subtracted 720 from IR 202 to yield

$$Z_{f_0} = \quad (11)$$

$$IR - \left[IR - \frac{IR \cdot X_{f_0}}{|X_{f_0}|^2} X_{f_0} - \frac{IR \cdot Y_{f_0}}{|Y_{f_0}|^2} Y_{f_0} \right] = \frac{IR \cdot X_{f_0}}{|X_{f_0}|^2} X_{f_0} + \frac{IR \cdot Y_{f_0}}{|Y_{f_0}|^2} Y_{f_0}$$

where z_{f_0} 722 is the component of MR 202 at the f_0 frequency. The magnitude calculation 560 has z_{f_0} 722 as an input and calculates

$$|Z_{f_0}| = \quad (12)$$

$$\left| \frac{IR \cdot X_{f_0}}{|X_{f_0}|^2} X_{f_0} + \frac{IR \cdot Y_{f_0}}{|Y_{f_0}|^2} Y_{f_0} \right| = \sqrt{\frac{(IR \cdot X_{f_0})^2}{|X_{f_0}|^2} + \frac{(IR \cdot Y_{f_0})^2}{|Y_{f_0}|^2}}$$

which is equivalent to equation 8a, above.

FIGS. 8A–B illustrate an iterative embodiment of the frequency calculator 410 (FIG. 4) described above. An iterative frequency calculator 410 has an initialization 810, a signal component transform 820, an extrema detection 850, a resolution decision 860 and a resolution refinement 880 and provides a component frequency f_0 870. Initialization 810 defines a window around the pulse rate estimate PR and a frequency resolution within that window.

As shown in FIG. 8A, a signal component transform 820 has an initial frequency selection 822, a frequency cancellation 824 and an magnitude calculation 828. A decision block 830 determines if the magnitude calculation 828 has been performed at each frequency within the window. If not, the loop of frequency cancellation 824 and magnitude calculation 828 is repeated for another selected frequency in the window. The frequency cancellation 824 removes a frequency component from the IR sensor signal, as described with respect to FIG. 5, above. The magnitude calculation 828 determines the magnitude of the remainder signal, also described with respect to FIG. 5, above. If the decision block 830 determines that the remainder signal magnitudes have been calculated at each of the selected frequencies, then the signal component transform loop 820 is exited to the steps described with respect to FIG. 8B.

As shown in FIG. 8B, the extrema detector 850 finds a minima of a signal component transform 820 and a resolution decision block 860 determines if the final frequency resolution of a signal component transform is achieved. If not, resolution refinement 880 is performed. If the final resolution is achieved, the component frequency output f_0 is equated to the frequency of the minima 870, i.e. a signal component transform minima determined by the extrema detector 850.

Further shown in FIG. 8B, the resolution refinement 880 has a set frequency estimate 882, a window decrease 884 and a frequency resolution increase 888. Specifically, the frequency estimate 882 is set to a signal component transform minima, as determined by the extrema detector 850. The window decrease 884 defines a new and narrower window around the frequency estimate, and the frequency resolution increase 888 reduces the spacing of the selected frequencies within that window prior to the next iteration of a signal component transform 820. In this manner, a signal component transform 820 and the resulting frequency estimate are refined to a higher resolution with each iteration of signal component transform 820, extrema detection 850, and resolution refinement 880.

In a particular embodiment, the component calculation requires three iterations. A frequency resolution of 4 beats

per minute or 4 BPM is used initially and a window of five or seven selected frequencies, including that of the initial pulse rate estimate PR, is defined. That is, a window of either 16 BPM or 24 BPM centered on PR is defined, and a signal component transform is computed for a set of 5 or 7 selected frequencies evenly spaced at 4 BPM. The result is a frequency estimate f_1 . Next, the frequency resolution is reduced from 4 BPM to 2 BPM and a 4 BPM window centered on f_1 is defined with three selected frequencies, i.e. f_1-2 BPM, f_1 , and f_1+2 BPM. The result is a higher resolution frequency estimate f_2 . On the final iteration, the frequency resolution is reduced to 1 BPM and a 2 BPM window centered on f_2 is defined with three selected frequencies, i.e. f_2-1 BPM, f_2 , and f_2+1 BPM. The final result is the component frequency f_0 determined by a signal component transform to within a 1 BPM resolution. This component frequency f_0 is then used to calculate the oxygen saturation, SAT_{f_0} , as described above.

The signal component processor has been described above with respect to pulse oximetry and oxygen saturation measurements based upon a frequency component that optimizes signal energy. The signal component processor, however, is applicable to other physiological measurements, such as blood glucose, carboxy-hemoglobin, respiration rate and blood pressure to name a few. Further, the signal component processor is generally applicable to identifying, selecting and processing any basis function signal components, of which single frequency components are one embodiment, as described in further detail with respect to FIG. 9, below.

FIGS. 9–11 illustrate another embodiment of a signal component processor 900. As shown in FIG. 9, the processor 900 has an index calculator 910 and a measurement calculator 960. The index calculator has a sensor signal input S 902 and outputs a basis function index κ_0 912, as described with respect to FIG. 10, below. The measurement calculator 960 inputs the basis function index κ_0 912 and outputs a physiological measurement U_{κ_0} 962, as described with respect to FIG. 11, below. The processor 900 also has a basis function indicator 980, which is responsive to the sensor signal input S 902 and provides a parameter ϵ 982 that indicates a set of basis functions to be utilized by the index calculator 910, as described with respect to FIG. 10, below.

As shown in FIG. 10, the functions of the index calculator 910 are basis subset generation 1020, component cancellation 1040 and optimization calculation 1060. The basis subset generation 1020 outputs a subset Φ_{κ} 1022 of basis function waveforms corresponding to a set of selected basis function indices κ . The basis functions can be any complete set of functions such that

$$S = \sum_{\kappa} a_{\kappa} \Phi_{\kappa} \quad (13)$$

For simplicity of illustration purposes, these basis functions are assumed to be orthogonal

$$\langle \Phi_{\gamma}, \Phi_{\eta} \rangle = 0; \gamma \neq \eta \quad (14)$$

where $\langle \rangle$ denotes an inner product. As such

$$\alpha_{\kappa} = \langle S, \Phi_{\kappa} \rangle / \langle \Phi_{\kappa}, \Phi_{\kappa} \rangle \quad (15)$$

$$S_{\kappa} = \alpha_{\kappa} \Phi_{\kappa} \quad (16)$$

In general, the basis functions may be non-orthogonal. The subset of basis functions generated is determined by an input parameter ϵ 982. In the embodiment described with

respect to FIG. 5, above, the basis functions are sinusoids, the indices are the sinusoid frequencies and the input parameter ϵ 982 is a pulse rate estimate that determines a frequency window.

As shown in FIG. 10, the component cancellation 1040 generates a remainder output R_{κ} 1042, which is a set of remainder signals corresponding to the subset of basis function waveforms Φ_{κ} 1022. For each basis function waveform generated, component cancellation removes the corresponding basis function component from the sensor signal S 902 to generate a remainder signal. In an alternative embodiment, component cancellation 1040 is replaced with a component selection that generates a corresponding basis function component of the sensor signal S 902 for each basis function generated. The optimization calculation 1060 generates a particular index κ_0 912 associated with an optimization of the remainders R_{κ} 1042 or, alternatively, an optimization of the selected basis function signal components.

As shown in FIG. 11, the functions of the measurement calculator 960 are basis function generation 1120, component selection 1140, and physiological measurement calculation 1170. The component selection 1140 inputs the sensor signal S 902 and a particular basis function waveform Φ_{κ_0} 1122 and outputs a sensor signal component S_{κ_0} 1142. The physiological measurement 1170 inputs the sensor signal component S_{κ_0} 1142 and outputs the physiological measurement U_{κ_0} 962, which is responsive to the sensor signal component S_{κ_0} 1142. In the embodiment described with respect to FIG. 6, above, the basis functions Φ_{κ} are sinusoids and the index κ_0 is a particular sinusoid frequency. The basis function generation 1120 creates sine and cosine waveforms at this frequency. The component selection 1140 selects corresponding frequency components of the sensor signal portions, RD and IR. Also, the physiological measurement 1170 computes an oxygen saturation based upon a magnitude ratio of these RD and IR frequency components.

The signal component processor has been disclosed in detail in connection with various embodiments. These embodiments are disclosed by way of examples only and are not to limit the scope of the claims that follow. One of ordinary skill in the art will appreciate many variations and modifications.

What is claimed is:

1. A pulse oximeter system comprising:

an input capable of accepting a physiological signal; and a component processor capable of communicating with said input and comprising:

a first calculator capable of determining a basis function index from said signal; and

a second calculator capable of generating a basis function waveform according to said index, deriving a component from said sensor signal and said waveform, and generating a physiological measurement responsive to said component, wherein second calculator derives said component using at least the inner product of said sensor signal and said waveform.

2. A pulse oximeter system comprising:

an input capable of accepting a physiological signal; and a component processor capable of communicating with said input and comprising:

a first calculator capable of determining a basis function index from said signal; and

a second calculator capable of generating a basis function waveform according to said index, deriving a component from said sensor signal and said waveform, and generating a physiological measure-

11

ment responsive to said component, wherein said first calculator determines a basis function frequency as said basis function index, and said second calculator generates a sinusoid at said frequency as said basis function waveform.

3. The pulse oximeter system according to claim 2, wherein said first calculator derives a pulse rate estimate from said signal selects said frequency from a window including said pulse rate estimate.

4. The pulse oximeter system according to claim 2, wherein said second calculator generates an oxygen saturation value responsive to a magnitude of said component as said physiological measurement.

5. A signal processing method comprising the steps of:
receiving a sensor signal;
calculating an estimated pulse rate;
determining an optimization of said sensor signal proximate said estimated pulse rate;
defining a frequency corresponding to said optimization;
and

outputting a physiological measurement responsive to a component of said sensor signal at said frequency, and wherein said outputting step comprises the substeps of:
inputting a red (RD) portion and an infrared (IR) portion of said sensor signal;
deriving a RD component of said RD portion and an IR component of said IR portion corresponding to said frequency; and
computing an oxygen saturation based upon a magnitude ratio of said RD component and said IR component; and

wherein said deriving step comprises the substeps of:
generating a sinusoidal waveform at said frequency;
and
selecting said RD component and said IR component utilizing said waveform.

12

6. The signal processing method according to claim 5, wherein said selecting step comprises the substep of calculating the inner product between said waveform and said RD portion and the inner product between said waveform and said IR portion.

7. The signal processing method according to claim 6, wherein said selecting step comprises the substeps of:
canceling said waveform from said RD portion and said IR portion, leaving a RD remainder and an IR remainder; and

subtracting said RD remainder from said RD portion and said IR remainder from said IR portion.

8. A signal processor comprising:

a first calculator means for deriving an optimization frequency from a pulse rate estimate and a sensor signal; and

a second calculator means for deriving a physiological measurement responsive to a sensor signal component at said frequency,

wherein said first calculator means comprises:

a signal component transform means for determining a plurality of signal values corresponding to a plurality of selected frequencies within a window including said pulse rate estimate; and

a detection means for determining a particular one of said selected frequencies corresponding to an optimization of said sensor signal; and

wherein said second calculator means comprises:

a waveform means for generating a sinusoidal signal at said frequency;

a frequency selection means for determining a component of said sensor signal from said sinusoidal signal; and

a calculator means for deriving a ratio responsive to said component.

摘要(译)

信号处理器生成基函数并识别传感器信号的至少一个基函数分量，以便计算生理测量。信号处理器有利地应用于脉搏血氧测定法，以便直接计算氧饱和度并且计算稳健的氧饱和度测量值。具体地，可以在导出的脉搏率估计周围的窗口内计算信号分量变换。信号分量变换还可以利用正弦基函数，并且信号分量变换的优化可以在特定频率或一组频率处发生。产生该频率或频率组的正弦波形或波形以选择传感器信号的相关红色和红外分量，并根据这些分量的幅度比计算氧饱和度。
