(21) Appl. No.: **10/357,531**

Aspects of the present invention include systems and methods for indicating an amount of use of a pulse oximetry sensor. According to one embodiment, the system includes an oximeter that monitors the amount of use for a given sensor. The oximeter and/or the sensor may advantageously include a visual alarm, an audio alarm, a vibrational alarm, a power down function, or the like, which can be activated when a predetermined amount of use has expired. According to another embodiment, the system includes a sensor having a memory device storing a unique identifier.

SYSTEMS AND METHODS FOR INDICATING AN AMOUNT OF USE OF A SENSOR

REFERENCE TO RELATED APPLICATION

[0001] The present application claims priority benefit under 35 U.S.C. § 120 to and is a continuation of U.S. patent application Ser. No. 09/502,032, filed Feb. 10, 2002, entitled "A System for Indicating the Expiration of the Useful Operating Life of a Pulse Oximetry Sensor," which is a continuation-in-part of U.S. patent application Ser. No. 09/420,544, filed Oct. 19, 1999, entitled "Shielded Optical Probe and Method," which claimed a priority benefit to U.S. Provisional Patent Application Serial No. 60/150,922, filed Aug. 26, 1999, by the same title. The present application incorporates the foregoing disclosures herein by reference.

BACKGROUND OF THE INVENTION

[0002] 1. Field of the Invention

[0003] The present invention in general relates to sensors for measuring oxygen content in the blood, and, in particular, relates to an apparatus and method for monitoring the life of a pulse oximetry sensor.

[0004] 2. Background

[0005] Early detection of low blood oxygen is critical in a wide variety of medical applications. For example, when a patient receives an insufficient supply of oxygen in critical care and surgical applications, brain damage and death can result in just a matter of minutes. Because of this danger, the medical industry developed pulse oximetry, a noninvasive procedure for measuring the oxygen saturation of the blood. A pulse oximeter interprets signals from a sensor attached to a patient in order to determine that patient's blood oxygen saturation.

[0006] A conventional pulse oximetry sensor has a red emitter, an infrared emitter, and a photodiode detector. The sensor is typically attached to a patient's finger, earlobe, or foot. For a finger, the sensor is configured so that the emitters project light from one side of the finger, through the outer tissue of the finger, and into the blood vessels and capillaries contained inside. The photodiode is positioned at the opposite side of the finger to detect the emitted light as it emerges from the outer tissues of the finger. The photodiode generates a signal based on the emitted light and relays that signal to the pulse oximeter. The pulse oximeter determines blood oxygen saturation by computing the differential absorption by the arterial blood of the two wavelengths (red and infrared) emitted by the sensor.

[0007] The foregoing conventional sensor is typically detachable from the oximeter to allow for periodic replacement. Periodic replacement is advantageous for a wide variety of reasons. For example, the sensor can become soiled, thereby possibly inhibiting sensor sensitivity or causing cross-patient contamination. Furthermore, the electronic circuitry in the sensor can become damaged, thereby causing sensor failure or inaccurate results. Moreover, the securing mechanism for the sensor, such as an adhesive substrate, can begin to fail, thereby improperly positioning the sensor in proximity to a measurement site and providing inaccurate data. Accordingly, periodic replacement of the sensor is an important aspect of maintaining a sterile, highly sensitive, accurate pulse oximetry system.

[0008] However, a conventional pulse oximetry sensor is wholly reliant on an operator for timely replacement of soiled, damaged, or otherwise overused sensors. This approach is problematic not only from the standpoint of operator mistake or negligence, but also from the perspective of deliberate misuse for cost saving or other purposes.

[0009] Based on the foregoing, significant drawbacks exist in the reliance on the operator for the periodic replacement of conventional pulse oximetry sensors. Accordingly, a need exists for a pulse oximetry sensor having the ability to monitor its own usable life.

SUMMARY OF THE INVENTION

[0010] Accordingly, one aspect of the present invention is to provide an inexpensive, highly accurate sensor life monitoring system for monitoring the useful and safe life of a pulse oximetry sensor. According to one embodiment, the sensor life monitoring system includes a timer and a sensor life indicator. According to another embodiment, the timer includes a divide-by-n counter and a non-volatile RAM, while the sensor life indicator includes at least one LED or incandescent bulb.

[0011] Therefore, one aspect of the present invention is a pulse oximetry sensor comprising a drive connection carrying a drive signal, wherein the drive signal has pulses. The pulse oximetry sensor further comprises a timer connected to the drive connection and configured to generate a timer output signal after a predetermined number of pulses are generated in the drive signal; and a sensor life indicator connected to the timer output signal and configured to provide an indication when the timer output signal is generated. The pulse oximetry sensor further comprises an LED network connected to the drive connection and configured to project light through a measurement site when pulsed by the drive signal; and a photodetector configured to detect the projected light and output a signal representative of constituents or characteristics of the measurement site.

[0012] Another aspect of the present invention is a sensor life monitoring system comprising a timer connected to a sensor drive signal; and a sensor life indicator connected to the timer such that the sensor life indicator is configured to indicate the expiration of the useful or safe life of a pulse oximetry sensor.

[0013] Another aspect of the present invention is a pulse oximetry system that comprises a pulse oximeter; a sensor connected to the pulse oximeter; and a sensor life monitor connected to the sensor and configured to monitor the useful and safe life of the sensor.

[0014] Another aspect of the present invention is a method of manufacturing a sensor. The method comprises connecting a timer to one of a sensor input and a sensor output; and connecting an indicator to the timer such that when the timer expires, the indicator is activated.

[0015] Another aspect of the present invention is a method for monitoring the life of an oximetry sensor. The method comprises monitoring a parameter responsive to repeated use of a sensor. When the parameter indicates that the sensor has expired, the method generates an expiration indication.

[0016] Another aspect of the present invention is an oximetry sensor life indicator that comprises a non-volatile

counter connected to receive a drive signal having a plurality of transitions where the counter changes a count value in response to the transitions. The oximetry sensor life indicator further includes a sensible indicia connected to the counter, where the sensible indicia has a first state, and a second state and the sensible indicia changes from the first state to the second state to indicate the end of life of the oximetry sensor when the count value in the counter reaches a predetermined value.

[0017] Another aspect of the present invention is an oximetry system comprising an oximeter; a sensor attached to the oximeter through a cable; a timer connected to at least one of a sensor drive signal and a sensor return signal; and a sensor life indicator connected to the timer.

[0018] Another aspect of the present invention is an oximetry system comprising a sensor having a timer, wherein the timer produces a sensor expiration signal. An oximeter is connected to the sensor and is configured to receive the sensor expiration signal from the timer.

[0019] Another aspect of the present invention is an oximetry system comprising a sensor having a reset indicator. An oximeter is connected to the sensor and is configured to monitor whether the reset indicator has been set.

[0020] Another aspect of the present invention is a pulse oximetry system comprising a pulse oximeter and a sensor connected to the pulse oximeter. The sensor is adapted to measure a physiological parameter. The pulse oximetry system also comprises a memory device connected to the sensor and adapted to measure the useful life of the sensor.

[0021] Another aspect of the present invention is a pulse oximetry system comprising a sensor having an emitter, a detector, and a memory device storing a characteristic of the sensor. The pulse oximetry system also comprises a pulse oximeter connected to the sensor and adapted to read the characteristic of the sensor and the output of the detector. The pulse oximetry system also comprises a database connected to the pulse oximeter and adapted to store the characteristic along with a longevity measurement corresponding to the sensor.

[0022] For the purposes of summarizing the invention, certain aspects, advantages, and novel features of the invention have been described. Of course, it is to be understood that not necessarily all such advantages may be achieved in accordance with any particular embodiment of the invention. Thus, the invention may be embodied or carried out in a manner that achieves or optimizes one advantage or a group of advantages, as taught herein, without necessarily achieving other advantages as may be taught or suggested herein.

[0023] Other aspects and advantages of the invention will be apparent from the detailed description below and the appended claims.

BRIEF DESCRIPTION OF THE DRAWINGS

[0024] The present invention is described in more detail below in connection with the attached drawings, which are meant to illustrate and not limit the invention, and in which:

[0025] **FIG. 1** illustrates a block diagram of a typical oximetry system;

[0026] **FIG. 2** illustrates a block diagram of a sensor life monitoring system according to an embodiment of the invention;

[0027] **FIG. 3** illustrates a block diagram of the sensor life monitoring system of **FIG. 2**, according to another embodiment of the invention;

[0028] **FIG. 4** illustrates a block diagram of an oximetry system having a sensor life monitoring system, according to yet another embodiment of the invention;

[0029] **FIG. 5** illustrates a block diagram of an oximetry system having a sensor life monitoring system, according to yet another embodiment of the invention;

[0030] **FIG. 6** illustrates a flow diagram of the operation of a microprocessor of the oximetry system of **FIG. 5**;

[0031] **FIG. 7** illustrates a block diagram of an oximetry system having a sensor life monitoring system, according to yet another embodiment of the invention; and

[0032] **FIG. 8** illustrates a block diagram of an oximetry system having a sensor life monitoring system, according to yet another embodiment of the invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

[0033] The inventions are described in detail below with reference to the figures, wherein like elements are referenced with like numerals throughout.

[0034] **FIG. 1** illustrates a block diagram of a typical oximetry system **100** used to determine arterial oxygen saturation. The oximetry system **100** includes an oximeter **105** and a sensor **110** connected to the oximeter **105** via a patient cable **115**. The oximeter **105** includes a microprocessor (μp) **120**, a speaker **125** and a display **130**. The sensor **110** includes a drive connection **135** connected to at least one LED network **140**, a photo detector **145** connected to a return signal connection **150**, and a cable connector **155** housing one end of each of the drive connection **135** and the return signal connection **150**. As mentioned, the sensor **110** attaches to the oximeter **105** via the patient cable **115**. The patient cable **115** includes a sensor connector **160** for electrically mating with the cable connector **155** of the sensor **110**.

[0035] As previously mentioned, the typical oximetry system **100** produces a drive signal and transmits the drive signal through the patient cable **115** and the drive connection **135** to the LED network **140** such that light energy is transmitted from the LED network **140** through tissue. The photo detector **145** senses the light energy, which has now been attenuated by the blood in tissue, and sends a representative signal of the light energy back to the oximeter **105** through the return signal connection **150** and the patient cable **115**. The oximeter **105** analyzes the representative signal from the photo detector **145** to determine constituency and characteristics of the blood in the tissue.

[0036] The sensor **110** typically includes the foregoing electronic circuitry and an attachment mechanism formed to secure the electronic circuitry to a measurement site. The sensor **110** may be disposable, wherein the attachment mechanism is likely formed from an adhesive structure. Moreover, the sensor **110** may be reusable, wherein the

attachment mechanism is likely formed from a clip-on structure. Also, the sensor 110 may be a combination of the disposable and reusable type sensors, wherein a disposable attachment mechanism removably attaches the electronic circuitry such that the electronic circuitry is reusable. Furthermore, the sensor 110 may include an information element electrically connected to the LED network 140. Such an information element advantageously provides quality control, security, and identification functions.

[0037] An example of the combination sensor having an information element distributed in the disposable attachment mechanism is described in U.S. patent application Ser. No. 09/456,666, filed on Dec. 9, 1999, titled, "Responsible Pulse Oximetry Sensor," assigned to the assignee of the current application, and incorporated by reference herein.

[0038] FIG. 2 illustrates a block diagram of a pulse oximetry sensor 200, according to an embodiment of the invention. As shown in FIG. 2, the sensor 200 includes a wholly incorporated sensor life monitoring system 203. The sensor life monitoring system 203 includes a timer 205 and a sensor life indicator (SLI) 210. According to this embodiment, the timer 205 is electrically connected to the drive connection 135 such that the timer 205 also receives the drive signal from the oximeter 105. The timer 205 also connects to the sensor life indicator 210.

[0039] As the oximeter 105 drives the LED network 140, the timer 205 monitors the number of drive pulses produced and keeps a running count. After the oximeter 105 produces a predetermined number of drive signals, the timer 205 provides a signal to the sensor life indicator 210, such that the sensor life indicator 210 produces an indication that the sensor 200 has expired and should be replaced.

[0040] FIG. 3 illustrates a block diagram of an example of the sensor life monitoring system 203 of FIG. 2, according to one embodiment of the invention. As shown in FIG. 3, the timer 205 advantageously comprises a non-volatile counter. One embodiment of the non-volatile counter advantageously comprises a counter 300 having an output that connects to an input of a logic gate 302. An output of the logic gate 302 connects to an adder 304. As used herein, an "adder" can be an arithmetic unit, which may also be implemented as a subtractor or the like. The adder 304 connects to a non-volatile (NV) RAM 305 (A non-volatile RAM does not lose data when the power is turned off or otherwise terminated). An output of the NVRAM 305 reconnects as feedback to the adder 304. Also, an output of the most significant bit (MSB) of the NVRAM 305 connects to both an inverter 307 and the sensor life indicator 210. The inverter 307 connects as feedback to another input of the logic gate 302. Moreover, the output of the logic gate 302 activates or clocks the NVRAM 305.

[0041] According to one embodiment, the counter 300 comprises a divide-by-n counter, producing an incremental output count only after n input pulses, or transitions, of the drive signal. Using a divide-by-n counter advantageously reduces the capacity requirements of the NVRAM 305. Furthermore, according to one embodiment, the logic gate 302 is an AND gate, the adder 304 is a plus-one adder. Thus, each time the adder 304 receives an input, it adds one to the current count stored in the NVRAM 305. According to one embodiment, the NVRAM 305 is a seventeen-bit non-volatile memory that clocks, for example, on the trailing edge of the output of the logic gate 302.

[0042] According to an embodiment of the invention, the sensor life indicator 210 comprises a sensible indicia, such as visible light. For example, the sensible indicia may advantageously be an LED 310, or the like. Alternatively, the sensible indicia may be audible, vibrational, a power down of the sensor 200 or the oximeter 105, or the like.

[0043] The operation of the foregoing timer 205 and sensor life indicator 210 will be disclosed with reference to two differing time frames. The first time frame refers to when a new sensor 200 is initially attached to the oximeter 105 and provided with a drive signal. The second time frame refers to when the sensor 200 has previously been used, and a new drive signal is applied.

[0044] First Use of the Sensor 200

[0045] According to the foregoing embodiment, the sensor life monitoring system 203 initially functions as follows. The oximeter 105 outputs a drive signal at, for example, one kHz. The counter 300 comprises a divide-by-1000 counter that advantageously produces, for example, an output only after one thousand cycles of the drive signal, or every one second. Furthermore, assuming the count stored in the NVRAM 305 is initially zero, the output of the MSB of the NVRAM 305 is zero. The inverter 307 inverts the output of the MSB such that the logic gate 302 passes the output of the counter 300 to the adder 304. Thus, according to this example, the adder 304 receives a pulse every second from the counter 300. With each pulse, the adder 304 adds one to count stored in the NVRAM 305. Thus, after one second, the adder 304 places a one in the NVRAM 305. After another second, the adder 304 places a two in the NVRAM 305, and so forth until the NVRAM 305 fills to capacity, or the oximeter 105 ceases producing the drive signal. Both events are further discussed as follows.

[0046] Subsequent Use of the Sensor 200

[0047] When the oximeter 105 sends pulses to a previously used sensor 200, the NVRAM 305 will already have a previous count stored therein. The previous count is loaded into the adder 304 such that as the logic gate 302 outputs the foregoing signal every second, the adder 304 adds one to the previous count. For example, if the previous count were one hour, or 3,600 seconds, the first pulse received by the adder 304 from the counter 300 will store 3,601 in the NVRAM 305. Thus, much like an automobile odometer, the NVRAM 305 stores a running count, or times, the used life of the sensor 200.

[0048] When the count stored in the NVRAM 305 reaches capacity (in other words, sets the MSB), the output of the MSB switches. Therefore, the output of the inverter 307 switches such that the logic gate 302 blocks any future signals output from the counter 300 from reaching the adder 304. Moreover, the output of the MSB further activates the LED 310 such that the LED 310 indicates the sensor 200 has expired. This indication by the LED 310 signals the operator to replace the used sensor 200 with a new one. The indication advantageously provides multiple people with the knowledge that the sensor 200 should be changed. For example, doctors, nurses, visitors, and even the patient may perceive the indication that the sensor 200 has expired.

[0049] According to the foregoing embodiment where every second that the oximeter 105 sends drive pulses to the sensor 200, the seventeen-bit NVRAM 305 is incremented,

the MSB of the NVRAM 305 will set after 131,072 seconds, or, one day, twelve hours, twenty-four minutes and thirty two-seconds. In other words, according to this embodiment, the useful life of the sensor 200 expires after the sensor 200 has received drive pulses for a combined total of the foregoing time.

[0050] A skilled artisan will understand that a wide number of differing logic mechanisms may be employed in the foregoing embodiment. For example, employing different sized counters 300 or NVRAMs 305 will adjust the predetermined expiration time. Moreover, the counter 300 may advantageously divide by more than one thousand, thereby further reducing the capacity requirements of the NVRAM 305. Also, the timer 205 may advantageously comprise a non-volatile counter that has internal registers that retain their values when the power is turned off. Such non-volatile counters are available, for example, from Dallas Semiconductor Corporation of Dallas, Tex. These non-volatile counters may include, for example, Dallas Semiconductor's DS1602 or DS1603. In the foregoing embodiments employing a non-volatile counter, the adder 304 and the counter 300 may not be needed.

[0051] A skilled artisan will also understand that the sensor 200 may advantageously employ a wide variety of differing timers 205 and differing sensor life indicators 210. Moreover, the choice may advantageously coincide with particular types of the sensor 200. For example, a purely disposable sensor suggests a less costly solution than that of the reusable sensor because of manufacturing costs and the relatively short life of the disposable sensor. On the other hand, the combination sensor may incorporate a more expensive solution into the reusable portion of the electronic circuitry without dramatic cost changes to the disposable portion.

[0052] Moreover, a skilled artisan will recognize that the timer 205 may advantageously comprise a capacitor that is charged when the sensor 200 is connected to the oximeter 105. In such case, the capacitor has known discharge characteristics such that the voltage across the capacitor can be used to measure the useful life of the sensor 200. Also, rather than using the pulses of the drive signal, the timer 205 may employ an oscillator configured to trigger at the beginning of sensor use.

[0053] Further, the sensor life indicator 210 may include several LEDs of differing colors, such as green and red, to indicate whether the sensor 200 has expired. The sensor life indicator 210 may comprise an incandescent light, an audio or vibrational alarm, a digital or LCD display, or other sensible indicia. Moreover, the sensor life indicator 210 may include a blocking signal for automatically terminating the functionality of the sensor 200. For example, a logic gate may be advantageously added to the drive signal such that the logic gate has the drive signal as an input and has the output of the timer 205 as the another. When the output of the timer 205 is a logic level signaling expiration, the logic gate blocks the drive signal from passing, thus rendering the sensor 200 inoperative. The foregoing logic circuit may also be used to block the signal transferred through the return signal connection 150. On the other hand, the blocking signal may also comprise a fuse that once blown, renders the sensor 200 inoperative.

[0054] Accordingly, a skilled artisan may perceive a variety of differing devices to measure the longevity of the

sensor 200. Furthermore, the type of the sensor 200 may provide guidance on which of the wide variety of devices to use.

[0055] FIG. 4 illustrates a block diagram of yet another embodiment of an oximetry system 400 including a sensor life monitoring system 405. According to this embodiment, the sensor life monitoring system 405 employs the timer 205 and a return signal 410 to the oximeter 105. Similar to the foregoing embodiment, the timer 205 connects to the drive connection 135 and uses the pulses of the drive signal to measure the useful and safe life of the sensor 200. In contrast to the foregoing embodiment, the timer 205 then outputs an incremental count of pulses to the oximeter 105 via the return signal 410, the cable connector 155, the sensor connector 160, and the patient cable 115. In this embodiment, the microprocessor 120 of the oximeter 105 receives the incremental count from the timer 205 and compares the incremental count with a predetermined amount. If the count is greater than the predetermined amount, the microprocessor 120 issues an expiration indication of the sensor 200 through the oximeter 105.

[0056] A skilled artisan will recognize that the oximeter 105 may issue the expiration indication through a wide variety of devices including, but not limited to, those described in relation to the sensor life indicator 210 of FIGS. 2-3. Moreover, the oximeter 105 may take advantage of the more costly technology already associated therewith. For example, the oximeter 105 may issue the expiration indication by employing an audio alarm through the speaker 125, a visual alarm through the display 130, or a power-down function where the oximeter 105 is inoperable until the sensor 200 is replaced.

[0057] FIG. 5 illustrates a block diagram of yet another embodiment of an oximetry system 500 including a sensor life monitoring system 505. According to this embodiment, the sensor life monitoring system 505 employs a reset indicator 510 and the sensor life indicator 210, as an integral part of the sensor 200. The reset indicator 510 and the sensor life indicator 210 connect to the oximeter 105 through the cable connector 155, the sensor connector 160, and the patient cable 115. Also according to this embodiment, the microprocessor 120 includes a timer 515.

[0058] According to this embodiment, the microprocessor 120 measures the useful and safe life of the sensor 200. For example, the microprocessor 120 may track the pulses in the drive signal created by the microprocessor 120, or take advantage of a date/time function to measure actual time. Furthermore, the microprocessor 120 employs the reset indicator 510 on the sensor 200 to indicate whether the sensor 200 is newly attached or has previously expired. For example, the reset indicator 510 may comprise a one-bit memory or a fuse technology, wherein the one-bit memory is set, or the fuse is blown, when the sensor 200 first connects to the oximeter 105 through the mating of the cable and sensor connectors, 155 and 160 respectively.

[0059] As shown in FIG. 5, the sensor life indicator 210 remains an integral part of the sensor 200 and, therefore, may advantageously take any of the forms discussed above with reference to FIGS. 2 and 3. Preferably, the sensor life indicator 210 comprises the LED 310 of FIG. 3.

[0060] FIG. 6 illustrates a flow diagram 600 of the steps taken by the microprocessor 120 of the oximetry system 500

of FIG. 5, according to one embodiment of the invention. As shown in FIG. 6, the process begins when the oximeter 105 is activated to a sensing state by, for example, an operator, in a STEP 603. The oximeter 105 first checks the reset indicator 510, in a STEP 605, to determine whether the sensor 200 has been previously used. If the sensor 200 is new, the microprocessor 120 resets the timer 515, in a STEP 610, and sets the reset indicator 510 on the sensor 200, in a STEP 615. The microprocessor 120 then proceeds with normal operation, e.g., to output a drive signal to the sensor 200, in a STEP 620.

[0061] On the other hand, if in the STEP 605, the reset indicator 510 indicates that the sensor 200 has been previously used, or when the sensor 200 is in normal operation, in the STEP 620, the microprocessor 120 checks whether the timer 515 indicates the sensor 200 has reached its predetermined longevity, in a STEP 625. For example, the timer 515 may advantageously compare the number of drive pulses to a predetermined number to conclude whether the sensor 200 has expired.

[0062] If the sensor 200 has not expired, the microprocessor 120 again proceeds with normal operation, in the STEP 620. On the other hand, if the timer 515 indicates that the sensor 200 has expired, the microprocessor 120 activates the sensor life indicator 210, in a STEP 630, and then the process terminates, in a STEP 635.

[0063] One having ordinary skill in the art will understand that the microprocessor 120 may employ an interrupt driven mechanism for the timer 515. For example, during normal operation, the microprocessor 120 may not continually, or periodically, check the timer 515, as in the STEP 625. Rather, the microprocessor 120 may continually send drive pulses until the timer 515 generates an interrupt that instructs the microprocessor 120 to activate the sensor life indicator 210. A skilled artisan will appreciate that there are a wide number of mechanisms for generating microprocessor interrupts.

[0064] FIG. 7 illustrates a block diagram of yet another embodiment of an oximetry system 700 including a sensor life monitoring system 705. According to this embodiment, the oximetry system 700 is similar to that described in reference to FIG. 5. Like FIG. 5, the microprocessor 120 of the oximeter 105 includes the timer 515, or timer-like functions. Also, the sensor life monitoring system 705 advantageously employs the reset indicator 510 to ensure replacement of new sensors when the sensor 200 expires. Moreover, like FIG. 4, the oximetry system 700 employs the oximeter 105 to provide an expiration indication once the sensor 200 expires.

[0065] Thus, according to one embodiment, the microprocessor 120 of the oximeter 105 checks the reset indicator 510 to ensure the sensor 200 has not previously been used. Then, the microprocessor 120 drives the LED network 140 and tracks the timing functions. When the predetermined number of drive pulses is reached, the microprocessor 120 employs various mechanisms on the oximeter 105 to generate the expiration indication. For example, the microprocessor 120 may use the speaker 125 or the display 130, even power down the oximeter 105, or the like, to create the expiration indication.

[0066] FIG. 8 illustrates a block diagram of yet another embodiment of an oximetry system 800. According to this

embodiment, the oximetry system 800 includes a sensor life monitoring system 805 having a memory device 810. The memory device 810 is preferably a single wire memory device having a unique identifier, such as memory devices commercially available from companies such as Dallas Semiconductor Corporation. For example, Dallas Semiconductor's DS2401 includes a unique, 64-bit identification number. In this way, the memory device 810 can uniquely identify the sensor 200 from all other sensors.

[0067] The oximetry system 800 further includes the microprocessor 120 of the oximeter 105 connected to a memory, such as a database 815. According to the preferred embodiment, the database 815 is stored locally in the memory of the oximeter 105. The oximeter 105 reads the unique identifier from the memory device 810 on the sensor 200 and, if necessary, creates a record in the database 815 corresponding to the unique identifier. Then, as the sensor 200 is used, the oximeter 105 accesses the record corresponding to the unique identifier so as to update the information relating to the longevity of the sensor 200. This information may advantageously include timing information, such as a decremented or incremented chronological count. The information may also, or alternatively, include the number of times the sensor 200 has been used, the number of drive signals the sensor 200 has received, or other similar methods of determining the amount of use for the particular sensor 200 having the particular unique identifier.

[0068] According to this embodiment, when the information stored in the database 815 reaches a predetermined threshold for a particular unique identifier, the oximeter 105 advantageously produces the expiration indication in a similar manner to that described in reference to FIG. 4. For example, the oximeter 105 may issue the expiration indication by employing an audio alarm through the speaker 125, a visual alarm through the display 130, or a power-down function that renders the oximeter 105 inoperable. These expiration indications may advantageously continue until the sensor 200 having the unique identifier is replaced with one having a different unique identifier.

[0069] Although the database 815 is described as being stored in memory associated with the oximeter 105, the invention is not meant to be limited thereby. Rather, a skilled artisan would recognize that the database 815 may advantageously be stored in a central location, such as a remote server connected through a wide number of known technologies, such as a local or wide area network, the internet, or other communications connection. In this way, a monitoring authority, ranging from a pair of pulse oximeters, to one or a number of hospitals, to a particular sensor manufacturer, and the like, can monitor the useful life of sensors identified through their unique identifier stored in the memory device 810.

[0070] As an alternative to, or in addition to, the foregoing embodiment where the memory device 810 includes a unique identifier, the memory device 810 may include the ability to store data. Again, such memory devices are commercially available from, for example, Dallas Semiconductor Corporation, and typically allow for read/write access over a single wire. For example, Dallas Semiconductor's DS2502 has the ability to accept new data for non-volatile storage.

[0071] According to this embodiment, the oximeter 105 reads data stored in the memory device 810 relating to

longevity, and updates that data according to use. For example, the oximeter **105** may read the memory device **810** of sensor **200** and determine that the sensor **200** has been in use for one increment of time, such as one minute. After the sensor **200** has been used for another increment of time, such as another minute as measured by the oximeter **105**, the oximeter may write to the memory device **810** such that the memory device **810** now reflects that the sensor **200** has been used for two minutes. This periodic read and write to the memory device **810** continues until the memory device **810** reflects a longevity measurement greater than a predetermined threshold. At that time, the oximeter **105** may advantageously issue the foregoing expiration indication.

[0072] A skilled artisan would recognize that a wide variety of timing schemes may be implemented using the foregoing read/write technique. For example, the oximeter **105** may advantageously decrement from a predetermined threshold stored in the memory device **810**. On the other hand, the memory device may store the number of times the sensor **200** has been used, the number of drive signals the sensor **200** has received, or other similar methods of determining the amount of use for the particular sensor **200**.

[0073] Moreover, a skilled artisan would recognize that the foregoing embodiments may advantageously be combined such that the memory device **810** includes both the unique identifier and the ability to store other data. This other data may advantageously include the foregoing read/write timing data, manufacturing data such as sensor type, manufacturing source indication, tolerance levels, operating characteristics, and the like.

[0074] Although the foregoing invention has been described in terms of certain preferred embodiments, other embodiments will be apparent to those of ordinary skill in the art. For example, a skilled artisan will recognize the distinction in the foregoing embodiments between those components described as being integral with the sensor **200**, or on-sensor components, and those components described as not being integral with the sensor **200**, or off-sensor components. The on-sensor components may advantageously be housed in the disposable, reusable, or combination sensors. With respect to the combination sensors, the on-sensor components may be advantageously housed in the disposable portion, the reusable portion, or both portions, of the combination sensor.

[0075] Further, the off-sensor components may be housed in any of the longer lasting components associated with the oximeter **105**. For example, the off-sensor components may be advantageously located on the sensor connector **160** or on the patient cable **115** where they are readily seen, heard, or felt by the operator or patient.

[0076] Moreover, the foregoing embodiments incorporating the memory device **810** of FIG. 8 may advantageously be combined with those embodiments describing the sensor life indicator **210** housed on the sensor **200**. In such embodiment, the oximeter **105** may advantageously provide the expiration indication to the sensor life indicator **210** when the oximeter **105** determines that the sensor **200** had expired.

[0077] Additionally, other combinations, omissions, substitutions and modifications will be apparent to the skilled artisan in view of the disclosure herein. Accordingly, the present invention is not intended to be limited by the

reaction of the preferred embodiments, but is to be defined by reference to the appended claims.

What is claimed is:

1. A method of monitoring when a pulse oximetry sensor has been used beyond a predetermined amount, the method comprising:

monitoring with an electronic device an amount of use of a pulse oximetry sensor; and

activating an expiration indicator when the amount is at or near a predetermined amount of use.

2. The method of claim 1, wherein the activation occurs when the amount is less than the predetermined amount.

3. The method of claim 1, wherein the activation occurs when the amount is greater than the predetermined amount.

4. The method of claim 1, wherein the activation occurs when the amount is the same as than the predetermined amount.

5. The method of claim 1, wherein the amount comprises a value representative of a number of pulses sent to the pulse oximetry sensor.

6. The method of claim 1, wherein the amount comprises an amount of time.

7. The method of claim 1, wherein the electronic device comprises an oximeter.

8. The method of claim 1, wherein the activating comprises activating at least one of an audio and visual alarm on the electronic device.

9. The method of claim 1, wherein the activating comprises outputting a signal to the pulse oximetry sensor.

10. The method of claim 1, further comprising identifying the pulse oximetry sensor.

11. The method of claim 10, wherein the identifying includes setting a memory device on the pulse oximetry sensor.

12. The method of claim 11, wherein the memory device comprises a fuse.

13. The method of claim 10, wherein the identifying includes reading a memory device on the pulse oximetry sensor.

14. The method of claim 13, wherein the memory device stores identifying information.

15. The method of claim 10, further comprising updating a current amount of use for the identified pulse oximetry sensor on the electronic device.

16. A method of determining an amount of use of a medical sensor, the method comprising:

determining whether a medical sensor being used is new; when the medical sensor is new, resetting a timer;

incrementing the timer during use of the medical sensor; and

when the timer is proximate to a predetermined amount, activating an indicator configured to illustrate that the use of the medical sensor is proximate the predetermined amount.

17. The method of claim 16, wherein the indicator is activated when the use is less than the predetermined amount.

18. The method of claim 16, wherein the indicator is activated when the use is greater than the predetermined amount.

19. The method of claim 16, wherein the indicator is activated when the use is the same as than the predetermined amount.

20. The method of claim 16, wherein the determining comprises accessing a memory identifying whether the medical sensor has been used.

21. The method of claim 16, wherein the determining comprises accessing a memory identifying the medical sensor.

22. A pulse oximeter comprising:

an output conductor configured to connect to a pulse oximetry sensor; and

a microprocessor configured to monitor transitions supplied to the output conductor and when a representative value of the transitions approaches a predetermined amount, to activate an indicator indicating that use the pulse oximetry sensor has approached the predetermined amount.

23. The pulse oximeter of claim 22, wherein the microprocessor activates the indicator when the representative value is less than the predetermined amount.

24. The pulse oximeter of claim 22, wherein the microprocessor activates the indicator when the representative value is greater than the predetermined amount.

25. The pulse oximeter of claim 22, wherein the microprocessor activates the indicator when the representative value is the same as than the predetermined amount.

26. The pulse oximeter of claim 22, wherein the microprocessor activates the indicator by outputting a signal to the pulse oximetry sensor.

27. The pulse oximeter of claim 22, wherein the microprocessor activates the indicator by activating an audio alarm.

28. The method of claim 22, wherein the microprocessor activates the indicator by activating a visual alarm.

29. An electronic medical device configured to send signals to and receive signals from a sensor, the electronic medical device comprising:

a microprocessor;

an output configured to communicate with a sensor;

a program executing on the microprocessor, wherein the program instructs the microprocessor to identify the sensor, monitor the use of the sensor and provide at least one of an audio and visual alarm when the sensor reaches a predetermined amount of use.

30. The electronic medical device of claim 29, wherein the program instructs the microprocessor to identify the sensor by accessing identification information related to the sensor.

31. The electronic medical device of claim 30, wherein the identification information comprises a settable memory device.

32. The electronic medical device of claim 30, wherein the identification information is stored in a memory on the sensor.
