A device for sensing the temperature profile of a hollow body organ includes a catheter and hollow a guidewire carrying a thermal sensor. The hollow guidewire is configured to displace the thermal sensor radially relative to the catheter when unconstrained and can be rotated about the longitudinal axis of the catheter. When constrained within the catheter, the guidewire can be advanced to a region of interest in hollow body organ. The catheter can be withdrawn, leaving the guidewire in place in an expanded configuration wherein the thermal sensor contacts the inner wall of the hollow body organ. The guidewire is moveable to sense the temperature at multiple locations. The thermal sensor can be replaced with an electrode for sensing the impedance profile of the hollow body organ.

FIG. 10

DEVICE FOR SENSING TEMPERATURE PROFILE OF A HOLLOW BODY ORGAN

TECHNICAL FIELD OF THE INVENTION

[0001] This invention relates generally to invasive medical devices and more particularly to devices for sensing the temperature of the interior wall of a hollow body organ such as a blood vessel.

BACKGROUND OF THE INVENTION

[0002] Acute ischemic syndromes involving arterial blood vessels, such as myocardial infarction, or heart attack, and stroke, frequently occur when atherosclerotic plaque ruptures, triggering the formation of blood clots, or thrombosis. Plaque that is inflamed is particularly unstable and vulnerable to disruption, with potentially devastating consequences. Therefore, there is a strong need to detect and locate this type of plaque so that treatment can be initiated before the plaque undergoes disruption and induces subsequent life-threatening clotting.

[0003] Various procedures are known for detecting and locating plaque in a blood vessel. Angiography is one such procedure in which X-ray images of blood vessels are generated after a radiopaque dye is injected into the blood stream. This procedure is capable of locating plaque in an artery, but is not capable of revealing whether the plaque is the inflamed, unstable type.

[0004] Researchers, acting on the theory that inflammation is a factor in the development of atherosclerosis, have discovered that local variations of temperature along arterial walls can indicate the presence of inflamed plaque. The temperature at the site of inflammation, i.e., the unstable plaque, is elevated relative to adjacent plaque-free arterial walls.

[0005] Using a tiny thermal sensor at the end of a catheter, the temperature at multiple locations along an arterial wall were measured in people with and without atherosclerotic arteries. In people free of heart disease, the temperature was substantially homogeneous wherever measured: an average of 0.65 degrees F. above the oral temperature. In people with stable angina, the temperature of their plaques averaged 0.19 degrees F. above the temperature of their unaffected artery walls. The average temperature increase in people with unstable angina was 1.23 degrees F. The increase was 2.65 degrees F in people who had just suffered a heart attack. Furthermore, temperature variation at different points at the plaque site itself was found to be greatest in people who had just had a heart attack. There was progressively less variation in people with unstable angina and stable angina.

[0006] The temperature heterogeneity discussed above can be exploited to detect and locate inflamed, unstable plaque through the use of cavity wall profiling apparatus. Typically, cavity wall profiling apparatus are comprised of temperature indicating probes such as thermocouples, thermistors, fluorescence lifetime measurement systems, resistance thermal devices and infrared measurement devices.

[0007] One problem with conventional cavity wall profiling apparatus is that they usually exert an undue amount of force on the region of interest. If the region of interest cannot withstand these forces, it may be damaged. The inside walls

of a healthy human artery are vulnerable to such damage. Furthermore, if inflamed, unstable plaque is present it may be ruptured by such forces.

[0008] Another problem with conventional cavity wall profiling apparatus is that they can only measure the temperature at one specific location. In order to generate a map of the cavity temperature variation, one would need to move the temperature indicating probe from location to location. This can be very tedious, can increase the risk of damaging the vessel wall or rupturing vulnerable plaque, and may not resolve temporal characteristics of the profile with sufficient resolution. An array of probes could be employed but that could be very big and heavy.

SUMMARY OF THE INVENTION

[0009] According to one aspect of the invention, a device is provided for sensing the temperature profile of a hollow body organ. The device includes a catheter, a hollow guidewire, and a temperature sensor disposed on or within the guidewire. The guidewire has a relaxed configuration externally of the catheter that is formed to provide contact with the wall of the hollow body organ. The guidewire also has a contracted configuration internally of the catheter and is of a lesser diameter than the catheter.

[0010] According to another aspect of the invention, the device is used by contracting the guidewire elastically and constraining the guidewire within the catheter. The catheter and guidewire are advanced to a region of interest in a hollow body organ. The catheter is withdrawn to expose the distal portion of the guidewire in a relaxed configuration in contact with the hollow body organ. The guidewire is moved longitudinally and rotated, continuously or continually, to sense the temperature of the hollow body organ at multiple locations.

[0011] Further aspects and advantages of the present invention are apparent from the following description of a preferred embodiment referring to the drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

[0012] In the drawings,

[0013] **FIG. 1** is a perspective view of a preferred embodiment of the present invention;

[0014] **FIG. 2** is a longitudinal sectional view of an arterial hollow body organ in which the embodiment of **FIG. 1**, also shown in longitudinal section, is deployed;

[0015] **FIG. 3** is a longitudinal sectional view of an arterial hollow body organ in which another preferred embodiment of the present invention, also shown in longitudinal section, is deployed;

[0016] **FIG. 4** is a perspective view of yet another preferred embodiment of the present invention;

[0017] **FIG. 5** is a perspective view, partially in section, of a further preferred embodiment of the present invention;

[0018] **FIG. 6** is a perspective view of yet another preferred embodiment of the present invention;

[0019] **FIG. 7** is a longitudinal sectional view of an arterial hollow body organ in which another preferred embodiment of the present invention, shown in perspective, is deployed;

[0020] FIG. 8 is a perspective view of a further preferred embodiment of the present invention;

[0021] FIG. 9 is a perspective view of another preferred embodiment of the present invention; and

[0022] FIG. 10 is a longitudinal sectional view of an arterial hollow body organ in which yet another preferred embodiment of the present invention, shown in perspective, is deployed.

DESCRIPTION OF THE PREFERRED EMBODIMENT

[0023] FIG. 1 shows a device 10 for profiling the wall of a hollow body organ. Device 10 includes a lumened catheter 12 having a central lumen 14, a hollow guidewire 16 that defines a conduit comprising a tubular helix formed of metal wire 18 or the like in the shape of a coil defining a central lumen (not shown), and a thermal sensor 20 disposed at the terminal end of the distal portion of guidewire 16. Conventional conductors or other signal carrying structures (not shown) are provided to convey signals from the thermal sensor 20 along guidewire 16 and out of the proximal portion of guidewire 16 for connection to appropriate signal processing apparatus that converts the signals to a temperature indication. Thermal sensor 20 can be a thermocouple, a thermistor, or an infrared radiation sensor, for example, and is secured by appropriate mechanical or adhesive means to the terminal end of guidewire 16.

[0024] Hollow guidewire 16 is made of thin wire 18 wound, for example around a mandrel, into small helical coils of desired diameter that lie tightly adjacent one another to form a hollow tube having a central passageway or lumen therethrough. Guidewire 16 has an outer diameter somewhat less than the inner diameter of catheter 12 to permit guidewire 16 to slide freely within the lumen 14 of catheter 12. In addition, guidewire 16, in its relaxed configuration, is shaped in the form of a bend 22 at the distal portion thereof, the bend 22 being spaced from the terminal end of guidewire 16 at which thermal sensor 20 is disposed. Consequently, thermal sensor 20 is displaced radially from the longitudinal axis 24 of guidewire 16 and catheter 12 when guidewire 16 is in the relaxed, bent configuration. Through external manipulation, guidewire 16 in the relaxed, bent configuration can be made to rotate about axis 24, continuously or continually, depending on the response time for the sensor, thereby causing thermal sensor 20 to traverse a circumferential or helical path about axis 24 while providing temperature information. Guidewire 16 can be deformed elastically into a substantially straight configuration, i.e., without bend 22, under force. When the force is removed, guidewire 16 returns to the relaxed, bent configuration.

[0025] Guidewire 16 can be constructed of spring steel that can be deformed into a relatively straight configuration when withdrawn into catheter 12, but which springs back to its bent configuration when extruded from catheter 12 and released from constraint. Another way is to construct guidewire 16 of superelastic nitinol and take advantage of the martensitic transformation properties of nitinol. Guidewire 16 can be inserted into catheter 12 in its straight form and kept cool within the catheter by the injection of cold saline through catheter 12 and over guidewire 16. Upon release of guidewire 16 into the bloodstream, it will warm up and change to its austenite memory shape based on the

well-known martensitic transformation by application of heat and putting the material through its transformation temperature.

[0026] Guidewire 16 can also be made out of a composite such as a nitinol tube within the guidewire structure. In this fashion, the martensitic or superelastic properties of nitinol can be combined with the spring steel characteristics of the spring and lead to a desirable composition. Other suitable materials for guidewire 16 include copper, constantin, chromel or alumel.

[0027] FIG. 2 shows device 10 deployed in a hollow body organ comprising an arterial blood vessel 26 having an endothelium 28 forming the inner wall thereof. Only the distal portion of guidewire 16 that extends beyond catheter 12 is shown. Electrical conductor 32 extends through lumen 30 of guidewire 16. Conductor 32 is electrically insulated from the coils 18 of guidewire 16 so that guidewire 16 comprises one conductor and conductor 32 comprises another conductor or lead of the thermal sensor 20 which can be a thermocouple or thermistor. The conductors convey signals from the thermal sensor 20 to the proximal end of guidewire 16 for connection to appropriate signal processing apparatus that converts the received signals to a temperature indication.

[0028] In use, the guidewire 16 and thermal sensor 20 of the preferred embodiment of device 10, as shown in FIGS. 1 and 2, are inserted into the lumen 14 of catheter 12 from the proximal end, thereby constraining guidewire 16 in a substantially straight configuration with the thermal sensor 20 near the distal end of catheter 12. Using conventional percutaneous insertion techniques, access to the blood vessel 26 is obtained surgically. Catheter 12, with guidewire 16 and thermal sensor 20 disposed within, is advanced through the blood vessel 26 to the region of interest.

[0029] Catheter 12 is slowly withdrawn while guidewire 16 is secured against movement relative to the patent such that guidewire 16 emerges from the distal end of catheter 12 and reverts to the relaxed, bent configuration within the blood vessel 26. Guidewire 16 remains substantially fixed in the axial direction relative to the blood vessel 26 as catheter 12 is withdrawn, with the re-formed bent distal portion of guidewire 16 springing gently radially outwardly into contact with the vessel wall 28.

[0030] With guidewire 16 exposed and thermal sensor 20 lying in contact with the wall 28 of blood vessel 26, the thermal sensor 20 senses the localized temperature of the vessel wall 26 at the region where the thermal sensor 20 is situated. By slowly withdrawing guidewire 16 into catheter 12 while simultaneously rotating guidewire 16 about its longitudinal axis, thermal sensor 25 can be made to traverse a helical path around the inner wall 28 of the blood vessel 26, permitting temperature measurements to be taken at intervals of different regions of the vessel wall 28. Depending upon the response time of thermal sensor 20, rotation can be intermittent or continuous, as needed. By withdrawing and rotating the guidewire 16 at constant rates, the location of the thermal sensor 20 relative to the distal end of the catheter 12 can be determined as a function of time, so that a temperature profile of the blood vessel 26 can be mapped, provided the response time of the thermal sensor is relatively short.

[0031] Once the mapping is completed, the guidewire 16 is withdrawn fully into catheter 12, re-sheathed and con-

strained in a substantially straight configuration. Catheter 12 can then either be withdrawn from the blood vessel 26 or repositioned to another region of interest within the hollow body organ for further mapping of the temperature profile at that region.

[0032] FIG. 3 shows a second preferred embodiment of a device 10' for profiling the wall of a hollow body organ. Device 10' can be deployed in a hollow body organ in a manner similar to the embodiment of device 10 shown in FIGS. 1 and 2 and described above with respect to structure and use. Components of device 10' that are similar in structure and function to corresponding components of device 10 of FIGS. 1 and 2 are designated by like primed numerals. The description of device 10 above applies also to device 10' unless described otherwise below.

[0033] Device 10' includes a second thermal sensor 36 disposed at the outside of bend 22' and exposed for contact with the inner wall 28' of vessel 26'. A second electrical conductor 38 is electrically insulated the conductor 32' and from the wire 18' of guidewire 16' so that guidewire 16' comprises one conductor and conductor 38 comprises another conductor of the thermocouple or thermistor of thermal sensor 36 for conveying signals from the thermal sensor 36 to the proximal end of guidewire 16 for connection to appropriate signal processing apparatus that converts the signals to a temperature indication. Wire 18' of guidewire 16' is a conductor common to thermal sensors 20' and 36.

[0034] Device 10' of FIG. 3 can be used in a manner substantially similar to the manner of use described above with respect to device 10 of FIGS. 1 and 2, except that thermistors 20' and 38 simultaneously traverse intertwined helical paths in contact with the inner wall 28' of hollow body organ 26'. Consequently, the temperature profile of the inner wall 28' can be mapped more quickly because data can be gathered from different locations simultaneously.

[0035] FIG. 4 shows yet another preferred embodiment of a device 210 for profiling the wall temperature of a hollow body organ. Device 210 can be deployed in a hollow body organ in the manner described above with respect to the embodiments of devices 10 and 10' shown in FIGS. 1, 2 and 3 and described above. Components of device 210 that are similar in structure and function to corresponding components of device 10 of FIGS. 1 and 2 are designated by like reference numerals in the 200 series but having the same last two digits. The description of device 10 above applies also to device 210 unless described otherwise below.

[0036] Device 210 of FIG. 4 includes one thermal sensor 40 disposed at the outside of a dogleg bend 42 that is spaced distally from bend 222 and from the terminal end of guidewire 216. Thermal sensor 40 is exposed for contact with the inner wall 228 of vessel 226. An electrical conductor (not shown) is electrically insulated from the wire 218 of guidewire 216 so that guidewire 216 comprises one conductor and the electrical conductor comprises another conductor of the thermocouple or thermistor of thermal sensor 40 for conveying signals from the thermal sensor 40 to the proximal end of guidewire 216 for connection to appropriate signal processing apparatus that converts the signals to a temperature indication. Unlike the embodiments of devices 10 and 10' of FIGS. 1, 2 and 3, device 210 includes only a thermistor at dog-leg bend 42 and no thermistor at the terminal end of guidewire 216 or at bend 222.

[0037] Device 210 of FIG. 4 can be used in a manner substantially similar to the manner of use described above with respect to device 10 of FIGS. 1 and 2.

[0038] FIG. 5 shows a further preferred embodiment of a device 310 for profiling the wall temperature of a hollow body organ. Device 310 can be deployed in a hollow body organ in the manner described above with respect to the embodiments of device 10 shown in FIGS. 1 and 2 and described above. Components of device 310 that are similar in structure and function to corresponding components of device 10 of FIGS. 1 and 2 are designated by like reference numerals in the 300 series but having the same last two digits. The description of device 10 above applies also to device 310 unless described otherwise below.

[0039] Device 310 of FIG. 5, rather than having externally exposed thermal sensors as in the embodiments of FIGS. 1 through 4 above, includes a thermal sensor 50 disposed within the lumen 330 of hollow guidewire 316 and in thermal contact with the coiled wire 318 that comprises guidewire 316. Thermal sensor 50 is located at a dogleg bend 52 that is spaced between bend 322 and the distal end of guidewire 316. Guidewire 316 also includes bend 54 between bend 52 and the distal end of guidewire 316. Bends 322, 52 and 54 together cause the distal portion of guidewire 316 to assume the shape of a question mark when in a relaxed configuration. In such a configuration, bend 52 and bend 54 contact opposite sides of the inner wall of the hollow body organ. The spring nature of guidewire 316 urges bend 52 in contact with the hollow body organ. Insulated electrical conductors 56 and 58 are operatively connected to the thermocouple or thermistor of thermal sensor 50 for conveying signals from the thermal sensor 50 to the proximal end of guidewire 316 for connection to appropriate signal processing apparatus that converts the signals to a temperature indication.

[0040] Device 310 of FIG. 5 can be used in a manner substantially similar to the manner of use described above with respect to device 10 of FIGS. 1 and 2.

[0041] FIG. 6 shows another embodiment of a device 410 for profiling the wall temperature of a hollow body organ. Device 410 is an alternative configuration of the device 310 of FIG. 5, in which bend 454 extends in a direction opposite to that of bend 54, such that the terminal end portion of guidewire 416 extends axially away from catheter 412. Bend 454 serves a purpose similar to that of bend 54 of device 310 of FIG. 5, i.e., to assure that bend 452, at which thermal sensor 450 is located, remains in contact with the inner wall of the hollow body organ when deployed therein.

[0042] FIG. 7 shows yet another embodiment of the present invention. Temperature sensing device 510 is carried by hollow guidewire 516 which extends outwardly from the distal end of catheter 512 and includes thermal sensor 550, e.g., a thermistor at a dogleg bend 552 spaced from bend 522 which is situated between the sensor-carrying bend 552 and the distal end portion of catheter 512. The distal end portion of guide wire 516 terminates in a generally crescent-shaped loop and is rotatable, continuously or continually, as desired, to sense the temperature of the endothelium 528 lining the wall of blood vessel 526 in the vicinity of plaque deposit 592.

[0043] FIG. 8 shows a further embodiment of a device 610 for profiling the wall temperature of a hollow body

organ. Device **610** comprises another alternative configuration of the device **310** of **FIG. 5**, in which guidewire **616** is shaped as a plurality of loops **60** with a plurality of thermal sensors **62** located within guidewire **616** at each location along the loops **60** that would contact the wall of the hollow body organ when disposed therein.

[0044] **FIG. 9** shows yet another embodiment of a device **710** for profiling the wall temperature of a hollow body organ. Device **710** includes a lumened catheter **712** and a hollow guidewire **716**. The inner surface of lumen **730** of guidewire **716**, at a bend **742** similar to bend **42** of device **210** of **FIG. 4**, is lined with a layer of black paint **70** which is in turn lined with a thermochromic material **72** that is sensitive to a change of temperature of the guidewire **716**. The color of the thermochromic material **716** varies as a function of temperature.

[0045] Disposed within lumen **730** of guidewire **716**, inwardly of thermochromic material **72**, is an optical probe **74** including an illuminating optical fiber **76** having a radially emitting diffuser **78** at the distal end thereof, and a sensing optical fiber **80** having a conically beveled distal end **82** for collecting light. An illuminating electromagnetic radiation source connected to the proximal end of illuminating optical fiber **76** provides illuminating radiation that is guided by optical fiber **76** to the region of interest within the hollow body organ, and diffused radially by diffuser **78** to illuminate the interior of lumen **730**, particularly thermochromic material **72**. The illuminating radiation can be in the visible, infrared or ultraviolet portions of the spectrum. Radiation from diffuser **78** is differentially absorbed and reflected by thermochromic material **72**, according to the color of material **72** which is indicative of the temperature of guidewire **716** in contact with the wall of the hollow body organ in the region of interest.

[0046] The light reflected from thermochromic material **72**, having wavelengths indicative of the color thereof, is collected by distal end **82** and directed toward the proximal end of sensing optical fiber **80**. An appropriate optical reflectance spectrometry device connected to the proximal end of sensing optical fiber **80** generates an electrical signal indicative of the color, and therefore temperature, of thermochromic material **72**.

[0047] **FIG. 10** shows yet another embodiment of a device **810** suitable for profiling the impedance of the wall of a hollow body organ. Device **810** includes a catheter **812** within which is disposed a guidewire **816** having a dog-leg bend in the distal portion thereof. Device **810** is similar in configuration to the embodiment of device **210** of **FIG. 4**, and like components are indicated by like reference numerals in the 800 series but having the same last two digits. Unlike device **210** of **FIG. 4**, device **810** does not employ thermal sensing, but rather employs impedance sensing for profiling the wall of a hollow body organ. An electrode **90** at the outside of the dog-leg bend of guidewire **816** is in electrical contact with guidewire **816** and in electrical contact with the inner wall **828** of the hollow body organ **826**. Guidewire **816** comprises a conductor operatively connected to an external impedance measuring device that has a ground terminal electrically connected to the body in which the hollow body organ is located. A small electrical current is applied via guidewire **816** and electrode **90** to the inner wall **828** at the region of contact therebetween. The impedance of

the electrical path through the body, including through the region of interest in the hollow body organ **826**, can be measured and recorded. By moving guidewire **816** relative to the hollow body organ **826** as described above with respect to other embodiments, the impedance of the wall of the vessel **826** can be mapped. Any change of impedance along the wall **828** indicates the presence of an anomaly in the wall, such as a plaque **92**.

[0048] Although the present invention has been described in detail in terms of preferred embodiments, no limitation on the scope of the invention is intended. The scope of the subject matter in which an exclusive right is claimed is defined in the appended claims.

I claim:

1. A device for sensing the temperature profile of a hollow body organ, comprising:

a catheter having a longitudinal axis;

a hollow guidewire being disposable in a relaxed configuration externally of the catheter, and in a contracted configuration internally of the catheter; a temperature sensor connected to the guidewire and moveable therewith, the temperature sensor being displaced laterally relative to the longitudinal axis of the catheter when the guidewire is in the relaxed configuration.

2. The device of claim 1, wherein the hollow guidewire comprises a tubular helix.

3. The device of claim 1, wherein the hollow guidewire comprises a material having martensitic transformation properties.

4. The device of claim 3, wherein the hollow guidewire comprises nitinol.

5. The device of claim 1, wherein the hollow guidewire comprises an elastic material.

6. The device of claim 5, wherein the hollow guidewire comprises spring steel.

7. The device of claim 1, wherein the temperature sensor is a thermocouple.

8. The device of claim 7, wherein the temperature sensor comprises one leg of the thermocouple and the guidewire comprises another leg of the thermocouple.

9. The device of claim 1, wherein the temperature sensor is a thermistor.

10. The device of claim 1, wherein the temperature sensor comprises a thermochromic material.

11. The device of claim 10, wherein the thermochromic material is in thermal contact with the lumen of the hollow guidewire.

12. The device of claim 11, wherein the temperature sensor further includes an optical probe for sensing the color of the thermochromic material.

13. The device of claim 12, wherein the optical probe includes an illumination device for illuminating a region of interest of the hollow guidewire.

14. The device of claim 13, wherein the optical probe includes a sensing device for sensing reflected radiation from the thermochromic material.

15. The device of claim 14, wherein the reflected radiation is in the visible spectrum.

16. The device of claim 14, wherein the reflected radiation is in the infrared spectrum.

17. The device of claim 14, wherein the reflected radiation is in the ultraviolet spectrum.

18. The device of claim 1 wherein the temperature sensor is adapted for rotational displacement about the longitudinal axis of the catheter while in contact with the hollow body organ.

19. A device for sensing the impedance profile of a hollow body organ, comprising:

a catheter having a longitudinal axis;

a hollow guidewire being disposable in a relaxed configuration externally of the catheter, and in a contracted configuration internally of the catheter; an electrode connected to the guidewire and moveable therewith, the electrode being displaced laterally relative to the longitudinal axis when the guidewire is in the relaxed configuration.
