filed on Dec. 15, 2006.

An invention is disclosed for locating a region of interest in the calcaneus. A method and apparatus are disclosed that use a pair of ultrasound transducers for ultrasound assessment of various properties of bone. The invention includes positioning the transducers on the medial and lateral sides of the heel, respectively. The positioning is based on a size of a portion of the body of a subject upon whom the ultrasound assessment of the calcaneus is to be made. In a presently preferred embodiment of the invention, the length of the foot from the back to the head of the first metatarsal is used in conjunction with a proportionality constant and an angle, to position the pair of transducers. The positioning so obtained leads to the ability to make both (i) reproducible measurements and (ii) to be able to compare the results obtained in one person with another, because relatively analogous portions of the highly heterogeneous calcanei are assessed in both. In an alternative embodiment of the invention, a single transducer is positioned similarly on the heel, operating in pulse-echo mode.

ULTRASONIC BONE ASSESSMENT APPARATUS AND METHOD

RELATED U.S. APPLICATIONS

[0001] This application claims priority to pending U.S. Provisional Patent Application Ser. No. 60/874,654, filed Dec. 13, 2006, the entire disclosure of which is incorporated herein by reference and claims priority to pending U.S. Provisional Patent Application Ser. No. 60/875,088, filed Dec. 15, 2006, the entire disclosure of which is incorporated herein by reference.

FIELD OF THE INVENTION

[0002] The present invention relates generally to apparatus and method for non-invasively and quantitatively evaluating bone tissue in vivo. More specifically, the invention pertains to osteoporosis diagnosis, bone fracture risk assessment, and bone fracture diagnosis using an ultrasound apparatus and method. Even more specifically, the invention relates to a method and apparatus for locating a region of interest within a calcaneus that allows for both reproducible and comparative measurements of a set of ultrasound parameters associated with a given subject or set of subjects.

BACKGROUND OF THE INVENTION

[0003] In recent years, ultrasound has received a great deal of attention as a new technique for noninvasive assessment of bone, and numerous attempts have been made to use ultrasound energy for evaluating the condition of bone tissue in vivo, and thus for determining a measure of osteoporosis and assessing bone fracture risk.

[0004] In particular, Hoop discloses in U.S. Pat. No. 3,847,141 a device to measure bone density as a means for monitoring calcium content of the involved bone. A pair of opposed ultrasonic transducers is applied to opposite sides of a subject's finger, such that recurrent pulses transmitted via one transducer are "focused" on the bone, while the receiver response of the other transducer is similarly "focused" to receive pulses that have been transmitted through the bone. The circuitry in Hoop is arranged such that filtered reception of one pulse triggers the next pulse transmission; the filtering is by way of a bandpass filter, passing components of received signals in the 25 kHz to 125 kHz range only; and the observed frequency of retriggering is believed to be proportional to the calcium content of the bone. Thus Hoop is concerned only with what he defines to be transit time for pulses in the indicated band.

[0005] Pratt, Jr. deals with establishing, in vivo, the strength of bone in a live being such as a horse. In U.S. Pat. No. 4,361,154, the inventor solves the problem posed by measuring transit time from "launch" to "reception" of pulses of 0.5 MHz and 1.0 MHz through the bone and soft tissue, and from measurement of pulse-echo time, to thereby derive a measurement of transit time through bone alone. A data bank enables the evaluation of the bone condition from the measured transit times. U.S. Pat. No. 4,913,157, also granted to Pratt, Jr., operates on the same general principle of transit time/velocity deduction, using the latter preferred frequency of 2.25 MHz as the base frequency of pulsed "launchings" and a technique of matched filtering/Fourier transform filtering for further analyzing received pulses.

[0006] Palmer et al. disclose in U.S. Pat. No. 4,774,959 a bone measurement system deriving the slope of the relation

between ultrasonic frequency and attenuation of a sequence of tone signals. Being in the range of 200 kHz to 600 kHz, the signals are applied to one transducer and received by another transducer. The passage of the signals between the two transducers with and without the intervening presence of a heel bone is compared, with the assumption that the frequency/attenuation relation is a straight line, i.e., of constant slope.

[0007] U.S. Pat. No. 4,926,870 granted to Brandenburger discloses another in vivo bone analysis system which depends upon measuring transit time for an ultrasonic signal along a desired path through bone. A "canonical" waveform, determined by previous experience to be on the correct path, is used for comparison against received signals for transmission through the patient's bone, while the latter is reoriented until the received signal indicates that the bone is aligned with the desired path. Again, ultrasonic velocity through the patient's bone is assumed to have been determined from measured transit time.

[0008] Rossman et al. disclose in U.S. Pat. No. 5,054,490 an ultrasound densitometer for measuring physical properties and integrity of bone, upon determination of a transit time through bone. Alternatively, the Rossman et al. device compares absolute attenuation of specific frequency components of ultrasound signals through the bone with the absolute attenuation of the same frequency components through a medium of known acoustic properties.

[0009] Mele et al., disclose in U.S. Pat. No. 5,564,423, and in a subsequent related patent by Cadossi et al. (U.S. Pat. No. 6,436,042), disclose a device that measures the "amplitude dependent speed of sound" through a bony member in a living body. The method relies on the visual display of the received ultrasound signal, and the selection of a specific portion of the waveform for analysis.

[0010] Significant steps in advancing ultrasound bone assessment have been made by Kaufman et al. (in U.S. Pat. Nos. 5,259,384 and 5,651,363) and by Chiabrera et al. (in U.S. Pat. Nos. 5,785,656 and 5,879,301). In these patents, an estimate of a "bone transfer function" associated with a given bone is obtained in a statistically optimal fashion, and parametric estimates of the phase and attenuation functions associated with it are determined. The disclosed methods also describe the use of 2D array transducers for obtaining more reproducible estimates of the bone density, architecture, and fracture risk.

[0011] Notwithstanding the advances made in the past in previous attempts, as exemplified by the above-mentioned apparatuses and methods, there are still additional improvements needed in order to make ultrasound assessment a widely used technique for accurately and precisely assessing the bone density, architecture, quality, fracture diagnosis, and fracture risk of a subject.

SUMMARY OF THE INVENTION

[0012] It is accordingly a primary object of this invention to provide an improved method and apparatus for characterizing and determining non-invasively the properties of bone. A more particular though not limiting object of the invention is to provide a method and apparatus for non-invasive and quantitative evaluation of bone tissue in vivo, to make accurate and precise osteoporosis diagnosis and monitoring possible.

[0013] Another object is to meet the above objects in such a way that the bone tissue evaluation and the osteoporosis diagnosis may be performed in a much more convenient and reliable manner than those previously used.

[0014] A further object is to meet the above object in such a way that the bone tissue evaluation and the osteoporosis diagnosis may be performed with relatively more simple and inexpensive means than those previously used.

[0015] A still further object is to locate a region of interest of the calcaneus that is clinically relevant to assessment of osteoporosis, adjusts to the size of the calcaneus thereby maintaining the same relative region of interest across subjects, and at the same time maintains excellent reproducibility.

[0016] As compared with the prior art, the invention utilizes a novel method for reliably and reproducibly locating a region of interest (ROI) in a given subject in order to assist in achieving the indicated objectives. In particular, in the present invention a pair of ultrasound transducers are moved at a given angle and distance, the distance which is selected based on a measurement of a size of a portion of said subject's body.

[0017] Accordingly, the present invention utilizes a new configuration to identify a ROI of a calcaneus of a living being, to more conveniently, accurately and precisely determine the characteristics of the calcaneus—to thereby determine one or more of the bone properties such as fracture risk, strength, density, quality, and/or architecture of the bone. The advantage of such an approach is its inherent simplicity and convenience, as well as its increased sensitivity to the underlying state of the interrogated bone. This is in contrast to the prior art which can not extract as much information on the underlying bone in such a convenient and effective manner.

[0018] The invention in its presently preferred form of a method and apparatus of locating and identifying a region of interest of a calcaneus, achieves the foregoing objectives by reproducibly placing a pair of coaxially-aligned ultrasound transducers according to a size associated with a given subject. Prior methods have typically used a fixed ROI. For example, in this type of ROI-determination, ultrasound transducers are fixed relative to the fixture into which a subject's foot was placed. This can lead to a reasonable degree of reproducibility per se, but it suffers from the fact that a different portion of the calcaneus will generally be measured in different people. This is a consequence of the high degree of heterogeneity of the calcaneus (i.e., different regions within the calcaneus generally have very different bone densities, cortical thicknesses, and trabecular architectures) and also because of the variations in the size of the calcaneus among individuals. Thus, for a fixed placement of transducers, based for example, on a fixed distance from the back of the foot, this will generally lead to highly distinct relative portions of the calcanei associated with different individuals being measured, making meaningful comparisons among subjects quite difficult. An alternative has been described which relies on 2D arrays. Although a plausible technique for addressing the "fixed region of interest" problem, such systems are extremely complex and expensive.

[0019] In an attempt to develop a simple non-array apparatus and method for ultrasonically assessing a calcaneus, that offers both good reproducibility and measures relatively the same region of interest among a set of individuals, the present inventors have recognized several key points. The first, and this is the key observation, is that calcaneal size is closely related to the overall size of the foot. The other key observations are that the main location of interest is in the posterior portion of the calcaneus (as determined from data obtained by x-ray absorptiometers), and that this region of interest may generally be found on average at a fixed angle from the

horizontal (as determined from comparisons of the images produced by x-ray absorptiometers like the General Electric Lunar PIXI heel DXA machine with plain foot radiographs of many subjects).

[0020] In the presently preferred embodiment of the invention, and with additional reference to FIG. 1, a foot is placed on the surface of a horizontal portion of a fixture which also has a vertical portion against which the back of the foot is placed. A mechanical fixture holds a pair of (i.e., two) transducers coaxially aligned with one another facing the medial and lateral sides of the subjects heel. A threaded rod is then rotated so that an indicator is brought to be aligned with the head of the first metatarsal of the foot (namely, aligned with the head of the first metatarsal). The threaded rod is also connected, through a series of gears (including four pinion and two rack gears), to the transducer fixture so that the transducers are moved along a given angle a distance proportional to the distance between the back of the foot and the head of the first metatarsal. In the presently preferred embodiment, the given angle is equal to 50 degrees, and the proportionality constant, α , that is the amount of linear travel of the transducers along the given angle of 50 degrees, is 15/66, or approximately 0.23. The reference point for the transducers, in the presently preferred embodiment, is the corner closest to the foot at which the horizontal and vertical portions of the fixture meet. However, it should be appreciated that any point convenient as a reference point may be utilized and is within the scope of the present invention.

BRIEF DESCRIPTION OF THE DRAWINGS

[0021] FIG. 1 is a diagram showing the main components of an apparatus of the invention that is used to locate a region of interest of a calcaneus in a living being.

[0022] FIG. 2 contains engineering drawings of a set of parts that together with the parts in FIG. 3 can be used to construct one embodiment of the invention.

[0023] FIG. 3 contains engineering drawings of another set of parts that together with the parts in FIG. 2 can be used to construct one embodiment of the invention.

[0024] FIG. 4 shows an image of a plain radiograph of a portion of a foot including a calcaneus and the frame of reference used to compute the center of the region of interest.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

[0025] The invention is shown in FIG. 1 is used to locate a region of interest of a calcaneus in a living being for practicing a method of the invention. Specifically, it is intended for locating a region of interest in a calcaneus of a living being that would allow for non-invasively and quantitatively evaluating the status of bone tissue in vivo, as manifested through one or more of the quantities: bone-mineral density, architecture, quality, strength, and fracture risk at a given time. The components of the apparatus are, in general, commercially available from different sources and will be identified before or in the course of the detailed description of their total operation.

[0026] Referring to FIG. 1, a calcaneal bone (not shown) within a subject's heel 12 of a foot 10 to be analyzed in vivo is surrounded by a soft tissue having an outer skin surface (skin integument) 14. The heel 12 is to be interposed between two aligned and opposed acoustically coupled ultrasonic transducers 16 and 18 (not viewable behind foot 10) which

may be identically the same, and can be obtained from Valpey-Fisher Corp., located in Hopkinton, Mass., United States. As shown, transducer 16 is used for signal launching and the transducer 18 is the receiver for the launched signals after passing through the heel 12, its overlying skin 14, surrounding soft tissue, and also passes through the calcaneus itself (not shown).

[0027] As may be seen with further reference to FIG. 1, a subject's foot 10 is placed on a fixture 20, wherein said fixture contains a surface 22 upon which bottom of said foot rests, and a surface 24 upon which back of said foot rests. Implicit in the apparatus shown in FIG. 1 is a selection of a proportionality constant and selection of an angle. The selected proportionality constant, α , is the ratio of a linear distance a pair of ultrasound transducers are to be moved (with respect to or from a reference point) at the selected angle divided by a length associated with said subject's foot. In the presently preferred embodiment of the invention, the length associated with said subject's foot is the distance from the back of the heel to the head of the first metatarsal of the foot. With reference to FIG. 1, the location of the head of the first metatarsal is indicated by the marker 30.

[0028] Hence, in the presently preferred embodiment of the invention, a foot 10 is placed on the surface of a horizontal portion 22 of a fixture 20 which also has a vertical portion 24 against which the back of the foot is placed. Fixture 20 includes a hardware adapted to hold transducers 16, 18 coaxially aligned with one another facing the medial and lateral sides of the subject's heel 12. A threaded rod (underneath the horizontal portion 22 and shown in FIG. 2, 44) is then manually rotated with a crank 32 so that the marker 30 (and also shown in FIG. 2, 46) is brought to be aligned with the head of the first metatarsal of the foot. The threaded rod is also connected, through a series of gears (including in the presently preferred embodiment four pinion and two rack gears as shown in FIG. 2 and FIG. 3), to the transducer fixture so that the transducers are moved along a selected angle θ a distance proportional to the distance between the back of the foot and the head of the first metatarsal. With additional reference to FIG. 2, threaded rod 44 is rotated and causes a first rack 48 (to which the marker 46 is attached) to move linearly. With additional reference to FIG. 3, the first rack, shown as a dotted line 48 causes a set of four (4) pinion gears to rotate. One gear 50 is directly attached to the first rack. A second gear 51 serves to transfer the rotation in the proper direction to a third gear 52 which is mounted on a shaft to which a fourth gear 53. The fourth gear 53 is in contact with a second rack 60 that moves a piece to which the transducers are attached (see for example component 36 in FIG. 1). In the presently preferred embodiment of the invention, the desired proportionality constant, α , is achieved through appropriate selection of the ratio of the number of teeth in pinion gear four 53 to the number of teeth in pinion gear three 52; this is set as the ratio of 15/66 to achieve the desired motion and to locate the desired region of interest.

[0029] Therefore, in the presently preferred embodiment, and with additional reference to FIG. 4, the selected angle θ is equal to 50 degrees, and the proportionality constant, α , that is the amount of linear travel of the transducers from the reference point along the given angle of 50 degrees, is 15/66, or approximately 0.23. Therefore, for a ball length of 18 cm, the transducers would be moved a total linear motion (i.e., along a direction of 50 degrees with respect to the horizontal) of $0.23 \times 18 \text{ cm} = 4.14 \text{ cm}$, from a reference point. The refer-

ence point 61 for the transducers, in the presently preferred embodiment, is the corner closest to the foot at which the horizontal and vertical portions of the fixture meet. However, it should be appreciated that any point convenient as a reference point may be utilized and is within the scope of the present invention. It is important to appreciate that this procedure will position the transducers at a location overlying the calcaneus that is (1) reproducible and (2) at a position that allows comparisons of bone properties for different subjects to be made with each another. These two factors are key to making the invention disclosed herein useful for non-invasive ultrasound bone assessment, and whereby to achieve the indicated objectives. As may be seen in FIG. 4, the reference point in the presently preferred embodiment is the point at which the vertical and horizontal portions of the fixture meet, indicated by the large dot. The 'x', 62, denotes the center of the identified ROI, over which the center of the transducer or transducers would be placed. The distance d of the center of the ROI to the reference point is equal to a L , where α is the constant of proportionality and L is the size of the relevant portion of the body; in this presently preferred embodiment, α is 0.23 and $L = 18 \text{ cm}$, the distance from the back of the foot to the head of the first metatarsal. Note that the reference point 61 in this embodiment as shown by the "dot" in FIG. 4 may be understood to correspond to the origin of a frame of reference consisting of an x-axis along the bottom of the foot and a y-axis along the back of the foot, as shown. Note that the parts used to produce the presently preferred embodiment of the invention can be purchased commercially (e.g., from Small Parts, Inc. Small Parts, Inc. of Miami Lakes, Fla., USA) or fabricated by a machining company (e.g., Queen Screw and Manufacturing, Inc., of Waltham, Mass., USA).

[0030] Note that in this preferred embodiment of the invention the distance from the back of a foot to the head of the first metatarsal was used as a measure of foot length. It should be understood, however, that the present invention encompasses use of a number of measures of overall foot length, for example the distance between the back of the foot to the end of any of the toes, or some average of a set of such lengths. For example, a measure of foot length from the back of the foot to any point along the ball line (a line that extends from the head of the first metatarsal to the head of the fifth metatarsal) could also be utilized. Therefore, it should be understood that any measure of foot size should be considered to be within the scope of the present invention. This should also be understood to include a length associated with any part of the foot and ankle anatomy, including, for example, a length from the bottom of the heel to the ankle. Of course it is appreciated that with different lengths so defined that different proportions and relationships with transducer motion in general will be necessary. The presently preferred use of the back of the foot and the head of the first metatarsal is due to the ability to locate them both fairly easily as well as the potential artifactual nature associated with the use of the ends of the toes.

[0031] In addition, it should be understood that different angles (from the presently preferred selection of $\theta = 50^\circ$) may also be utilized in the present invention. It should be understood that different angle selections will generally lead to different regions of interest of the calcaneus over which the ultrasound transducers will be located. These distinct regions of interest may prove useful in different aspects of bone assessment, for example as in osteoporosis. For example, one region of interest may prove most useful for assessing changes in bone density while another region of interest may

prove most useful for monitoring therapeutic effects on fracture risk. It should also be understood that the values of the specified angle as well as the proportionality constant may be varied to achieve similar but different results (for example to monitor another portion of the calcaneus, or to take into account additional information as to optimal transducer placement), and as such should be considered to be within the scope of the present invention as well.

[0032] The invention as presently embodied (and with reference to FIGS. 1-3) utilizes manual rotary motion of a threaded rod, together with a set of gears (including rack and pinion) to achieve the desired motion and ultimate location of the transducers. It should be understood, however, that any mechanical device, with gears or without and which may be powered for electronically controlled motion or manual or spring powered motion, should also be considered to be within the scope of the present invention. It should also be understood, that although the present embodiment utilizes a fixed ratio of x and y motion (and thus the fixed angle), the present invention should also be understood to include use of nonlinear relationships between the x and y coordinates of the transducer location as a function of length. This may be advantageous when additional information is gained on locating the region of interest, as it may, for example, be necessary for very large or very small feet, or perhaps in distinguishing anatomical variations between men and women.

[0033] In yet a further embodiment of the invention, a length not necessarily associated with the foot may be used for purposes of locating a region of interest on the calcaneus. For example, the height of a person may be utilized. Moreover, in this alternative embodiment a set of lengths associated with a variety of (but at least one) bony members of the body is utilized in determining a region of interest of the calcaneus. In general, the set of lengths may be used to independently determine the x and y coordinates of the center of the region of interest. This may be expressed by the following set of equations or relationships:

$$x=f(L1,L2,L3,\dots,LN)$$

$$y=g(L1,L2,L3,\dots,LN)$$

where x and y are the location of the region of interest (again with respect to a reference point), and L1, L2, L3, . . . , LN are the sizes associated with N portions of the body, and where f and g may be suitable functions. Let L1=height, and L2=ball length of the foot; then in a presently preferred embodiment of the invention

$$x=a*L1$$

$$y=b*L2$$

[0034] As may be seen in this embodiment, the x and y coordinates may not necessarily utilize the same dimensions from a given portion of a body. It should be understood that the invention includes many possible combinations and lengths (sizes) by which to locate the region of interest as specified by x and y. It should further be appreciated that in general f and g may be linear or non-linear functions, and that one may be linear and the other non-linear and visa versa. Note also that a frame of reference must be chosen for identifying the values of x and y.

[0035] It should also be appreciated that the center of the location of the region of interest is specified in terms of a set of (x,y) coordinates with respect to a reference frame, and generally is a distance, d, from the origin of the reference

frame. It should be understood however that the actual translation or motion of the transducers will not in general be moved a distance d since the starting point of the transducer motion is generally not at the origin.

[0036] It should be further appreciated that in an alternative embodiment of the invention, the fixture does not have a vertical portion, but rather a reference mark on the horizontal portion, i.e., a surface of the fixture on which the bottom of the foot rests. It should also be understood that the horizontal surface may not be actually horizontal since it may be convenient to orient it at an angle so that the subject may be comfortable, for example at a 30 degree angle. Similarly, the "vertical portion" of a fixture upon which the back of the foot (heel) rests may not be vertical if the fixture itself is oriented at an angle. Additionally the horizontal surface upon which the bottom of the foot rests may also not be flat, since in some embodiments it may be advantageous to raise or lower the heel with respect to the toes.

[0037] Thus what is disclosed is

[0038] A method for locating a region of interest of a calcaneus within a foot of a subject, comprising the following steps:

[0039] a. Placing said subject's foot in a fixture, said fixture containing a surface upon which bottom of said foot rests, and a surface upon which back of said foot rests;

[0040] b. Selecting a proportionality constant, an angle, and a reference frame;

[0041] c. Identifying a size associated with said subject's foot;

[0042] d. Positioning a pair of ultrasound transducers on the medial and lateral sides, respectively, of a heel of said foot to a location that is a distance equal to said proportionality constant times said length at said angle with respect to said reference frame;

[0043] to thereby locate a region of interest of said subject's calcaneus.

[0044] A method for locating a region of interest of a calcaneus within a foot of a subject, comprising the following steps:

[0045] a. Placing said subject's foot in a fixture, said fixture containing a surface upon which bottom of said foot rests, and a surface upon which back of said foot rests;

[0046] b. Selecting relationships between x and y motions of a pair of ultrasound transducers, respectively, a reference frame, and identifying at least one size associated with a body portion of said subject;

[0047] c. Positioning said pair of ultrasound transducers on a side of a heel of said foot in accordance with said relationships to thereby locate a region of interest of said subject's calcaneus.

[0048] Apparatus for locating a region of interest of a calcaneus within a foot of a subject, said apparatus comprising:

[0049] a fixture comprising at least one surface and further comprising at least one ultrasound transducer, said fixture including further means for moving said at least one ultrasound transducer according to a set of relationships, wherein said set of relationships includes means for utilizing at least one size associated with a body portion of said subject, and wherein said set of relationships also include means for using a reference frame, whereby said region of interest may be located on said calcaneus within said foot of said subject.

[0050] It should be appreciated that an actual measurement of the length of the selected body portion is not always necessary. In the presently preferred embodiment, and with

additional reference to FIG. 1, indicator 30 is adjusted through use of crank 32 until it is positioned at the head of the first metatarsal of a foot; this brings, at the same time, the transducers 16, 18, to the desired location on the heel and to the desired region of interest of the calcaneus. In other embodiments, explicit use of the length of a body portion (e.g., overall height of a subject) would need to be measured and utilized. Both kinds of embodiments (i.e., with and without an explicit measurement of length or size of a selected body portion) should be considered to be within the scope of the present invention. Moreover, an embodiment which uses both kinds (i.e., with an explicit and without an explicit measurement of size) should also be considered to be within the scope of the present invention.

[0051] It should also be understood that the invention can be utilized with two distinct transducer configurations. The first is with two transducers placed on opposite sides of a subject's heel in a "thru-transmission" mode. In the second, only one transducer may be used, in a "pulse-echo" configuration. In both cases, the methods and apparatuses of the present invention should be understood to be able to locate a desired region of interest of the calcaneus. It also should be appreciated that both pulse-echo and thru-transmission modes can be utilized together with the methods and apparatuses of the present invention.

[0052] It should be further appreciated that the disclosed techniques can work with any number of ultrasound signal processing methods and parameters. Therefore, it should be appreciated that any set of ultrasound parameters may be utilized in conjunction with the methods and apparatuses of the present invention. In particular, the methods and apparatuses as disclosed in U.S. Pat. Nos. 5,259,384, 5,651,363, 5,785,656 and 5,879,301, as well as in U.S. Patent Application No. 20050197576, all of which are incorporated by reference hereinto, and should be understood to be applicable to the present invention.

[0053] It should be understood that the methods and apparatuses disclosed herein for locating a region of interest of a calcaneus within a foot of a subject can be utilized not only with ultrasound but with other applications as well, such as for x-ray bone densitometry. In this application, it may be useful for example to measure the thickness of the heel at the region of interest identified by the methods disclosed herein. In this alternative embodiment of the invention, then, ultrasound transducers are not utilized. Therefore what is disclosed is

[0054] A method for locating a region of interest of a calcaneus on a heel of a foot of a subject, comprising the following steps:

[0055] a. Placing said subject's foot in a fixture, said fixture containing a surface upon which bottom of said foot rests, wherein said surface has a reference mark for said placing of said foot;

[0056] b. Selecting a relationship between a set of (x,y) coordinates associated with a reference frame and at least one size associated with a body portion of said subject,

[0057] thereby locating a region of interest of said subject's calcaneus.

[0058] It should be further understood that a measurement of overall heel width at the identified region of interest may be of use in various applications, including but not limited to ultrasound bone assessment and x-ray bone assessment. Therefore, it should be understood that in an alternative

embodiment of the invention not only is the location of the region of interest identified but a heel width measurement at that location is performed.

[0059] It should also be noted that the (x, y) coordinates disclosed hereinabove generally correspond to a center of a region of interest. The region of interest may be of various shapes, such as circular or square. However, it should be understood that a variety of choices for region of interest shape can be made (e.g., triangular or trapezoidal), and that the (x,y) coordinates may be chosen to be not only at the "center" but at other relative locations, and that all of these embodiments should be considered to be within the scope of the present invention. In the presently preferred embodiment of the invention, the region of interest is circular and the (x,y) coordinates are at the geometric center of the circular region of interest.

[0060] The invention as described herein achieves the primary objectives of the inventors, namely to locate a region of interest that is clinically relevant to assessment of osteoporosis, adjusts to the size of the calcaneus thereby maintaining the same relative region of interest across subjects, and at the same time maintains excellent reproducibility. While several embodiments of the present invention have been disclosed hereinabove, it is to be understood that these embodiments are given by example only and not in a limiting sense. Those skilled in the art may make various modifications and additions to the preferred embodiments chosen to illustrate the invention without departing from the spirit and scope of the present contribution to the art. Accordingly, it is to be realized that the patent protection sought and to be afforded hereby shall be deemed to extend to the subject matter claimed and all equivalence thereof fairly within the scope of the invention.

What is claimed is:

1. A method for locating a region of interest of a calcaneus within a foot of a subject, comprising the following steps:

- a. Placing said subject's foot in a fixture, said fixture containing a surface upon which bottom of said foot rests, and a surface upon which back of said foot rests;
 - b. Selecting a proportionality constant, an angle, and a reference frame;
 - c. Identifying a size associated with said subject's foot;
 - d. Positioning a pair of ultrasound transducers on the medial and lateral sides, respectively, of a heel of said foot to a location that is a distance equal to said proportionality constant times said length at said angle with respect to said reference frame;
- to thereby locate a region of interest of said subject's calcaneus.

2. The method according to claim 1, wherein said size is a length from said back of said foot to a head of the first metatarsal of said foot.

3. A method for locating a region of interest of a calcaneus within a foot of a subject, comprising the following steps:

- a. Placing said subject's foot in a fixture, said fixture containing a surface upon which bottom of said foot rests, and a surface upon which back of said foot rests;
- b. Selecting relationships between x and y motions of a pair of ultrasound transducers, respectively, a reference frame, and identifying at least one size associated with a body portion of said subject;
- c. Positioning said pair of ultrasound transducers on the medial and lateral sides, respectively, of a heel of said

foot in accordance with said relationships to thereby locate a region of interest of said subject's calcaneus.

4. The method according to claim 3, wherein said at least one size includes a length from said back of said foot to a head of the first metatarsal of said foot.

5. A method for locating a region of interest of a calcaneus within a foot of a subject, comprising the following steps:

- a. Placing said subject's foot in a fixture, said fixture containing a surface upon which bottom of said foot rests;
- b. Selecting relationships between x and y motions of a pair of ultrasound transducers, respectively, and a reference frame, and identifying at least one size associated with a body portion of said subject;
- c. Positioning a pair of ultrasound transducers on the medial and lateral sides, respectively, of a heel of said foot in accordance with said relationships to thereby locate a region of interest of said subject's calcaneus.

6. The method according to claim 5, wherein said at least one size includes a length from said back of said foot to a head of the first metatarsal of said foot.

7. A method for locating a region of interest of a calcaneus within a foot of a subject, comprising the following steps:

- a. Placing said subject's foot in a fixture, said fixture containing a surface upon which bottom of said foot rests, and a surface upon which back of said foot rests;
- b. Selecting a proportionality constant, an angle, and a reference frame;
- c. Identifying a size associated with said subject's foot;
- d. Positioning an ultrasound transducer on a side of a heel of said foot at a location that is a distance equal to said proportionality constant times said length at said angle with respect to said reference frame;

to thereby locate a region of interest of said subject's calcaneus.

8. The method according to claim 7, wherein said size is a length from said back of said foot to a head of the first metatarsal of said foot.

9. The method of claim 7, wherein said side of a heel is a medial side.

10. The method of claim 7, wherein said side of a heel is a lateral side.

11. A method for locating a region of interest of a calcaneus within a foot of a subject, comprising the following steps:

- a. Placing said subject's foot in a fixture, said fixture containing a surface upon which bottom of said foot rests, and a surface upon which back of said foot rests;
- b. Selecting relationships between x and y motions of a pair of ultrasound transducers, respectively, a reference frame, and identifying at least one size associated with a body portion of said subject;
- c. Positioning an ultrasound transducer on a side of a heel of said foot in accordance with said relationships to thereby locate a region of interest of said subject's calcaneus.

12. The method according to claim 11, wherein said at least one size includes a length from said back of said foot to a head of the first metatarsal of said foot.

13. The method of claim 11, wherein said side of a heel is a medial side.

14. The method of claim 11, wherein said side of a heel is a lateral side.

15. A method for locating a region of interest of a calcaneus within a foot of a subject, comprising the following steps:

- a. Placing said subject's foot in a fixture, said fixture containing a surface upon which bottom of said foot rests;
- b. Selecting relationships between x and y motions of a pair of ultrasound transducers, respectively, and a reference frame, and identifying at least one size associated with a body portion of said subject;
- c. Positioning an ultrasound transducer on a side of a heel of said foot in accordance with said relationships to thereby locate a region of interest of said subject's calcaneus.

16. The method according to claim 15, wherein said at least one size includes a length from said back of said foot to a head of the first metatarsal of said foot.

17. The method of claim 15, wherein said side of a heel is a medial side.

18. The method of claim 15, wherein said side of a heel is a lateral side.

19. Apparatus for locating a region of interest of a calcaneus within a foot of a subject, said apparatus comprising:

- a fixture comprising at least one surface and further comprising at least one ultrasound transducer, said fixture including further means for moving said at least one ultrasound transducer according to a set of relationships, wherein said set of relationships includes means for utilizing at least one size associated with a body portion of said subject, and wherein said set of relationships also include means for using a reference frame, whereby said region of interest may be located on said calcaneus within said foot of said subject.

20. Apparatus according to claim 19, wherein said at least one size includes a length from a back of said foot to a head of the first metatarsal of said foot.

21. Apparatus according to claim 19, wherein said at least one transducer comprises a first transducer and a second transducer on a medial and a lateral side of a heel, respectively, of said foot of said subject.

22. A method for locating a region of interest of a calcaneus on a heel of a foot of a subject, comprising the following steps:

- a. Placing said subject's foot in a fixture, said fixture containing a surface upon which bottom of said foot rests, and a surface upon which back of said foot rests;
- b. Selecting a relationship between a set of (x,y) coordinates associated with a reference frame and at least one size associated with a body portion of said subject, thereby locating a region of interest of said subject's calcaneus.

23. The method of claim 22, including a further step of measuring said heel width.

24. A method for locating a region of interest of a calcaneus on a heel of a foot of a subject, comprising the following steps:

- a. Placing said subject's foot in a fixture, said fixture containing a surface upon which bottom of said foot rests, wherein said surface has a reference mark for said placing of said foot;
- b. Selecting a relationship between a set of (x,y) coordinates associated with a reference frame and at least one size associated with a body portion of said subject, thereby locating a region of interest of said subject's calcaneus.

摘要(译)

公开了一种用于定位跟骨中的感兴趣区域的发明。公开了一种方法和设备，其使用一对超声换能器来对骨的各种特性进行超声评估。本发明包括分别将换能器定位在脚跟的内侧和外侧。该定位基于对象的身体的一部分的尺寸，对其进行跟骨的超声评估。在本发明的当前优选实施例中，足部从第一跖骨的背部到头部的长度与比例常数和角度一起使用，以定位该对换能器。如此获得的定位导致能够进行 (i) 可再现的测量和 (ii) 能够将一个人与另一个人获得的结果进行比较，因为在两者中评估高度异质跟骨的相对类似部分。在本发明的另一个实施例中，单个换能器类似地定位在脚跟，以脉冲回波模式操作。
