A method for joining and holding closed a wound in bodily tissue, fastening junctions of wounds, tying off wounds, joining a foreign element to tissue, and altering the position of tissue using a barbed suture including sharp pointed ends. Each end of the suture includes barbs on that permit movement in an opposing direction to the barbs on the other end of the suture. This two-way barbed suture is used by the method of the present invention in applications including abdominal surgeries such as a Nissen fundoplication, laparoscopic uses such as stabilizing a bowel structure and performing a closure of a cystostomy, liver to bowel anastomosis, closure of an orifice of a Zenker's Diverticulum, endoscopic uses such as closure of ulcerative lesions or and post-procedural tissue defects, bladder wound closure, valve replacement surgery, device attachment, cosmetic surgery, and blood vessel wound closure.

SUTURE METHOD

RELATED APPLICATIONS

[0001] This application is a divisional application of U.S. patent application Ser. No. 10/065,256, filed Sep. 30, 2002, which is a continuation-in-part of U.S. patent application Ser. No. 09/896,455, filed Jun. 29, 2001, the contents of both of which are hereby incorporated by reference.

BACKGROUND

[0002] This invention relates generally to a method for joining bodily tissue in surgical applications and wound repair, and more particularly to a surgical suturing method for joining bodily tissue using a suture having a plurality of barbs which permit the suture to be pulled through the tissue in one direction but resisting movement of the suture relative to the tissue in the opposite direction.

[0003] Surgical or accidental wounds are typically closed with a length of filament introduced into the tissue by a sharp metal needle attached to one end of the filament. This device is known as a "suture". Sutures are used to make "stitches" to close the wound for holding tissues together for healing and regrowth. Sutures are used in surgical procedures for wound closure, to close the skin in plastic surgery, to secure damaged or severed tendons, muscles or other internal tissues, and in microsurgery on nerves and blood vessels. Generally, the suture needle is caused to penetrate and pass through the tissue pulling the suture through the tissue. The opposing faces of the tissue are then moved together, the needle is removed, and the ends of the suture are tied in a knot. The suture forms a loop as the knot is tied. The knotting procedure allows the tension on the filament to be adjusted to accommodate the particular tissue being sutured and control of approximation, occlusion, attachment or other conditions of the tissue. The ability to control tension is extremely important regardless of the type of surgical procedure being performed.

[0004] Suturing is a time-consuming part of most surgical procedures, particularly in microsurgery and endoscopic surgery where there is insufficient space to properly manipulate the suture. Loop sutures can leave scars where they penetrate skin. For adequate closure of some wounds, the suture material must be of a high tensile strength and thus a large diameter thereby increasing scarring. The loop suture also constricts blood flow to the tissue it surrounds, promoting necrosis of the wound margins which compromises healing and increases infection risks. Further, the tissue is distorted as it is secured by the suture loop due to excess tension on the knots. Localized tensions from the knots are the culprit for scar formation. The bulk of the knots are also an impediment to wound healing in internal applications.

[0005] Alternatives to conventional sutures for wound closure are known, including fasteners such as staples, clips, tacks, clamps and the like. The fasteners are usually positioned transversely across a wound for joining or approximating each side of adjacent tissue layers laterally. Fasteners have relatively high strength and save time, but are not as accurate as sutures and are bulky and may be painful to remove. Fasteners are also generally unsuitable for deeper layers of tissue. Moreover, fasteners do not provide the advantage of adjustable tension obtained by the knotting of a length of suture material.

[0006] Surface adhesive tapes and glues are often used on skin to hold small wounds closed to permit healing. However, these products have relatively low tensile strength and are not useful in many situations.

[0007] Other techniques proposed include electrical coagulation and lasers. However, no acceptable alternative has been found which offers the advantages of suturing and tying in most surgical procedures.

[0008] One possible alternative is a barbed suture. A barbed suture includes an elongated body having one or more spaced barbs projecting from the surface of the body along the length of the body. The barbs are configured to allow passage of the suture in one direction through tissue but resist movement of the suture relative to the tissue in the opposite direction. In wound closure, a barbed suture is passed through tissue at each of the opposed sides of a wound. The wound is closed by pushing the sides of the wound together with the barbs maintaining the sutures in place and resisting movement of the tissue away from this position. The advantage of using barbed sutures is the ability to put tension in the tissue with less slippage of the suture in the wound. The barbed suture spreads out the holding forces evenly thereby significantly reducing tissue distortion. Since knots do not have to be tied, there is a time savings and the elimination of suture knots improves cosmetic effects and promotes wound healing. Barbed sutures also allow better apposition of tissue since the incised or insulted tissues are brought together and secured with almost no movement immediately. Unlike the conventional suturing method wherein tension is applied by pulling on the end of the suture after placement, barbed sutures permit tissue to be approximated and held snug during suturing. This is especially advantageous in closing long incisions. The result is better healing when the tissue levels are harmoniously matched as the cosmetic effect is more pronounced at skin level. Moreover, if there is an accidental breakage of the barbed suture, the wound is minimally disturbed. With conventional sutures, dehiscence would occur.

[0009] Despite the advantages offered by barbed sutures, the tensile strength of a barbed suture is less than a loop suture of equivalent size. This is due to the reduced tensile strength resulting from imparting the barb structure onto the body of the suture, which reduces its effective diameter. This limitation is not significant since larger barbed sutures with greater tensile strength can be utilized. However, the conventional methods for introducing barbed sutures into tissue still do not exhibit the same biomechanical performance of looped sutures.

[0010] For the foregoing reasons there is a need for a suturing method for joining tissue in surgical applications and wound repair which is efficient and expedites the surgical procedure. Ideally, the new method allows a surgeon to suture in an efficient manner to quickly approximate tissue with appropriate tension. The new method should preserve blood flow, improve wound healing strength, prevent distortion of the tissue and minimize scarring. The method should also incorporate the self-retaining benefits of the barbed suture with the holding power of conventional suturing methods. A particularly useful method would be utilized in surgical applications where space is limited such as microsurgery, endoscopic surgery, or arthroscopic surgery.

SUMMARY

[0011] The present invention provides a way to close wounds, fasten junctions of tissue, tie off wounds, join a foreign element to tissue, mount a device to tissue, alter the position of tissue where there is only a single portion of tissue without a wound or junction, and perform other procedures. The methods of the present invention are performed with a two-way barbed suture. Specifically, the two-way barbed suture includes an elongated body, first and second sharp pointed distal ends for penetrating the tissue, and a plurality of barbs extending from the periphery of the body. The barbs on a first portion of the body between the first end of the suture and a first axial location on the body permit movement of the suture through the tissue in a direction of movement of the first end, and prevent movement of the suture relative to the tissue in a direction opposite the direction of movement of the first end. The barbs on a second portion of the body between the second end of the suture and a second axial location on the body, which is less than the distance from the second end to the first axial location, permit movement of the suture through the tissue in a direction of movement of the second end, and prevent movement of the suture relative to the tissue in a direction opposite the direction of movement of the second end.

[0012] In some embodiments of the present invention an insertion device is used to insert the barbed suture. Such an insertion device is tubular and has leading and trailing ends with openings therein. The suture is initially disposed in the insertion device. The first end of the suture is proximate to the leading end of the insertion device. Where no insertion device is used, the sharp pointed ends of the suture are used to insert the suture in tissue; while these ends may be embodied, or be referred to, as needles herein, it should be understood that the suture may terminate in any type of sharp pointed end.

[0013] Some embodiments provide a method for joining and holding portions of a stomach to each other in the performance of a Nissen fundoplication procedure. The Nissen fundoplication procedure requires grasping the fundus of the stomach at a proximal location and pulling the fundus around the esophagus, wrapping the fundus around the esophagus one time and attaching the proximal stomach to an apposing portion of the stomach. One method that uses the sharp pointed ends of the barbed suture to penetrate tissue comprises the steps of inserting the first pointed end of the suture into tissue of the proximal stomach and pushing the first end of the suture through the stomach tissue until the first end of the suture extends out of the tissue at an exit point on the exterior of the stomach. The first end of the suture is pulled to draw the first portion of the suture through the tissue until the second axial location is proximate to the point of insertion of the first end of the suture. A length of the first portion of the suture is left in the tissue between the point of insertion and exit point of the first end. The proximal stomach is gripped and the fundus is wrapped around the esophagus until the proximal stomach contacts an apposing portion of stomach. The second pointed end of the suture is inserted into tissue of the apposing stomach, and the second end of the suture is pushed through the stomach tissue until the second end of the suture extends out of the tissue at an exit point on the exterior of the stomach. The second end of the suture is pulled to draw the second portion

through the tissue until the second axial location is proximate to the point of insertion of the second end of the suture and a length of the second portion of the suture is left in the tissue between the point of insertion and exit point of the second end.

[0014] In another embodiment of a Nissen fundoplication method, an insertion device is used. Again, the fundus is wrapped around the esophagus to form a junction with the apposing portions of stomach. Then the first pointed end of the suture and leading end of the insertion device are inserted into stomach tissue at a point laterally spaced from the junction and on a first side of the junction. The first end of the suture and leading end of the insertion device are pushed through the first side of stomach tissue and penetrate the stomach tissue on a second side of the junction until the portion of the suture between the first and second axial locations is proximate to the junction. The insertion device is removed by gripping and pulling the trailing end, leaving the suture in place.

[0015] Another embodiment for performing a Nissen fundoplication is provided using both sharp pointed ends of the suture, comprising the step of inserting the first pointed end of the suture into the tissue at a first side of the junction formed by the wrapping of the fundus around the esophagus. The first end of the suture is pushed through the tissue until the first end of the suture extends out of the tissue at an exit point in the face of the junction below the surface of the tissue at the first side of the junction. The first end is pulled out of the tissue, drawing the first portion of the suture through the tissue until the second axial location is at the point of insertion of the first end of the suture. A length of the first portion of the suture is left in the tissue between the point of insertion in the first side of the junction and the exit point in the face of the junction at the first side of the junction. The first end of the suture is then inserted into the face of the tissue below the surface of the tissue at a second side of the junction, and is pushed until the first end exits on the second side of the junction longitudinally spaced in a first direction from the insertion point in the first side of the junction. The first end of the suture is pulled out of the tissue and the first portion is drawn to bring the two sides of the junction together to a closed position along the first portion of the suture in the tissue. A length of the first portion of the suture is left in the tissue between the point of insertion in the first side of the junction and the exit point in the second side of the junction. The process is repeated similarly for the second end and second portion of the suture.

[0016] Another method for joining and holding portions of a stomach to each other in the performance of a Nissen fundoplication is provided, using the sharp pointed ends of the suture, which may be needles. The method comprises the steps of inserting the first pointed end of the suture into the stomach tissue below the surface of the stomach tissue at a first face of the junction at an initial point. The first end of the suture is pushed through the stomach tissue along a curvilinear path until the first end of the suture extends from the stomach tissue at an exit point in the first face of the junction. This exit point is longitudinally spaced in a first direction from the insertion point in the first face of the junction. The first pointed end of the suture is gripped and pulled until it is out of the stomach tissue, drawing the first portion of the suture through the stomach tissue until the second axial location is at the point of insertion of the first

end of the suture in the first face of the junction, leaving a length of the first portion of the suture in the stomach tissue of the junction. The first pointed end is inserted at a point below the surface of the stomach tissue in a second face of the junction, and pushed through the stomach tissue along a curvilinear path until the first end of the suture extends from the stomach tissue at an exit point in the second face of the junction below the surface of the stomach tissue. Again, the exit point is longitudinally spaced in the first direction from the insertion point in the second face of the junction. Then the first end of the suture is inserted at a point in the first face of the junction below the surface of the stomach tissue, and the above steps may be repeated for advancing along the junction in the first direction as necessary to one end of the junction. These steps are similarly repeated for the second end and second portion of the suture in a second direction. The initial point may be longitudinally spaced from the ends of the junction or adjacent to an end, and the first and second directions may be the opposite or same directions.

[0017] One embodiment provides a method for laparoscopically inserting a barbed suture with a laparoscopic insertion device, similar to the insertion device described above but included in a laparoscopic tool. The first pointed end of the suture and the leading end of the laparoscopic insertion device are inserted through an entry point in the skin, and then through the fat, fascia, muscle, and peritoneum into the abdominal cavity. The first end of the suture and leading end of the insertion device are pushed into the tissue in the abdominal cavity, and the insertion device is pulled at the trailing end to remove the insertion device. Additional embodiments include stabilizing a bowel structure, where the bowel structure is positioned and then stabilized by leaving the inserted suture in place in the bowel tissue and the abdominal wall, and for a closure for a cytostomy, in which the first and second ends and portions of the suture are inserted in urinary bladder muscularis.

[0018] Another embodiment involves a method for performing an anastomosis of the liver bile duct to a bowel structure, the bile duct having one end connected to the liver and a free end after having been severed, and the bowel structure having an opening in its wall made to receive the annular free end of the bile duct. One embodiment is performed with an insertion device as described above, with steps comprising placing the free end of the bile duct in contact with the opening in the bowel structure, and forming a junction at the annular contact area between the bile duct tissue and the bowel structure tissue. The first pointed end of the suture and the leading end of the insertion device are inserted into the tissue on one side of the junction. The first end of the suture and leading end of the insertion device are pushed through the tissue on one side of the junction, through the junction, and penetrate the tissue on the other side of the junction. The insertion device is gripped and pulled at the trailing end to remove the insertion device, leaving the suture in place in both the bile duct tissue and the bowel structure tissue. The previous steps are repeated as necessary to provide an anastomotic seal at the junction.

[0019] In another embodiment, a liver bile duct-to-bowel structure anastomosis is performed with needles. Here, the first pointed end of the suture is inserted into a first tissue at a point spaced from the junction of the duct and bowel structure. The first end of the suture is pushed through the first tissue until the first end of the suture extends out of the

first tissue at an exit point and penetrates a second tissue at a face of the junction. The first end of the suture is pushed until the first end of the suture extends out of the second tissue at an exit point spaced from the junction and spaced in a first direction along the circumference of the junction from the point of insertion of the first end of the suture in the first tissue. The first end of the suture is gripped and pulled out of a second tissue to draw the first portion of the suture through the first tissue and the second tissue while bringing the first tissue and the second tissue together to a closed position along the first portion of the suture. This pulling continues until the second axial location is at the point of insertion of the first end of the suture at the one side of the first tissue, leaving a length of the first portion of the suture in the first tissue and the second tissue between the point of insertion and the exit point. Then the first end of the suture is inserted into the second tissue at the exit point of the first end. The first end of the suture is pushed through the second tissue until the first end of the suture extends out of the second tissue at an exit point in the face of the junction and penetrates the first tissue. This pushing continues until the first end of the suture extends out of the first tissue at an exit point spaced from the junction and spaced along the circumference of the junction in the first direction from the immediately preceding point of insertion of the first end of the suture in the first tissue. Then first end of the suture is pulled out of the tissue to draw the first portion of the suture through the second tissue while bringing the first tissue and the second tissue together to a closed position along the first portion of the suture, and leaving a length of the first portion of the suture in the periphery between the point of insertion and the exit point. The above steps for the first end and first portion may be repeated to achieve an anastomotic seal. In addition, the steps described above are repeated similarly for the second end and second portion of the suture in a second direction.

[0020] In another embodiment, a method for tying off an appendiceal stump resulting from the performance of an appendectomy is provided, using needles. The appendix extends from the cecum of the large intestine and has a base with a circumference at the juncture of the appendix and the cecum. The first pointed end of the suture is inserted into tissue of the cecum proximate to the appendix base. The first end of the suture is pushed around the circumference of the base in one direction for at least one half of the circumference of the base until extending through an exit point in the tissue. The second pointed end of the suture is then inserted into tissue of the cecum proximate to the entry point of the first end, and the second end of the suture is pushed along the circumference of the base in the other direction for at least one half of the circumference of the base until extending through an exit point in the tissue. The appendix is excised, leaving the appendiceal stump. Then the ends of the suture are gripped and pulled, causing the suture to tighten around the appendiceal stump, and may invert the stump into the cecum.

[0021] Another embodiment provides a method for joining and holding closed the muscle layers that define the orifice of a Zenker's Diverticulum using an endoscopic insertion device, similar to the insertion device described above but included in an endoscopic tool. The Zenker's Diverticulum includes a sac extending from a proximal location of the esophagus near the pharynx, the sac having walls including a muscle layer common to the proximal

esophagus. The Zenker's Diverticulum may first be manually inverted into the esophagus, or left outside the esophagus. The first pointed end of the suture and the leading end of the endoscopic insertion device are inserted through an entry point in the esophageal muscle between the pharynx and the orifice, and spaced from the orifice. The first end of the suture and leading end of the insertion device are pushed through the muscle until the first end of the suture and the leading end of the insertion device extend out of the muscle at the orifice of the sac. Then the first pointed end of the suture and the leading end of the endoscopic insertion device are inserted through an opposing side of the orifice, and are pushed through the muscle until the second axial location is proximate to a central to the point of the orifice. The insertion device is gripped and pulled at the trailing end to remove the insertion device, leaving the suture in place. Optionally, the above steps may be repeated with additional sutures. The muscle on the two sides of the orifice is advanced together as necessary to close the orifice.

[0022] A method is provided for joining and holding closed ulcerative lesions or post-procedural tissue defects on an interior surface of a viscus, using an endoscopic insertion device as described above. The method comprises the step of inserting the first pointed end of the suture and the leading end of the endoscopic insertion device through an entry point in the tissue spaced from and on one side of the lesion. Then the first end of the suture and leading end of the insertion device are pushed through the tissue until the first end of the suture and the leading end of the insertion device extend out of the tissue at the lesion. The first pointed end of the suture and the leading end of the endoscopic insertion device are then inserted through an opposing side of the lesion, and are pushed until the second axial location is proximate to a central to the point of the lesion. The insertion device is gripped and pulled at the trailing end to remove the insertion device, leaving the suture in place. Again, optionally the above steps may be repeated. The tissue on the two sides of the lesion is advanced together to close the lesion.

[0023] In another embodiment, a method is provided for joining and holding closed a wound in urinary bladder muscularis tissue, using needles. The first pointed end of the suture is inserted into the tissue below the surface of the tissue at a first face of the wound at an initial point, which may for example be adjacent to one end or longitudinally spaced from both ends of the wound. The first end of the suture is pushed through the tissue along a curvilinear path until the first end of the suture extends from the tissue at a subcutaneous exit point in the first face of the wound and longitudinally spaced in a first direction from the insertion point in the first face of the wound. The first pointed end of the suture is gripped and pulled out of the tissue, drawing the first portion of the suture through the tissue until the second axial location is at the point of insertion of the first end in the first face of the wound and leaving a length of the first portion of the suture in the tissue of the wound. Then the first pointed end of the suture is inserted at a point below the surface of the tissue in a second face of the wound. The first end is pushed through the tissue along a curvilinear path until the first end extends from the tissue at an exit point in the second face of the wound below the surface of the tissue and longitudinally spaced in the first direction from the insertion point in the second face of the wound. The first end of the suture is inserted at a point in the first face of the wound below the surface of the tissue. The above steps are

repeated starting with the insertion of the first end of the suture in the first face of the wound to advance longitudinally along the wound in the first direction until reaching the end of the wound. Further, all of the above steps are repeated for the second end and second portion of the suture, in a second direction, starting with inserting the second end in the second face of the wound below the surface of the tissue and adjacent the initial point of insertion of the first end in the first face of the wound.

[0024] Another method is provided for joining and holding closed a wound in urinary bladder muscularis tissue, also using needles. The first pointed end of the suture is inserted into the muscularis tissue below the surface of the tissue of a first face of the wound at an initial point adjacent an end of the wound. The first end of the tissue is pushed through the tissue along a curvilinear path until the first end of the suture extends from the tissue at an exit point in the first face of the wound below the surface of the tissue and longitudinally spaced from the end of the wound in a direction toward the other end of the wound. The first pointed end of the suture is gripped and pulled out of the tissue, drawing the first portion of the suture through the tissue until the second axial location is at the point of insertion of the first end in the first face of the wound and leaving a length of the first portion of the suture in the tissue of the wound. The first end of the suture is then inserted into the second face of the wound below the surface of the tissue. The first end of the suture is pushed through the tissue along a curvilinear path until the first end extends from the tissue at an exit point in the second face of the wound below the surface of the tissue and longitudinally spaced from the insertion point in the second face of the wound toward the other end of the wound. The first end of the suture is inserted into the first face of the wound below the surface of the tissue, and the above steps are repeated starting with pushing the first end through the tissue until extending from an exit point in the first face of the wound, advancing longitudinally along the wound until reaching the other end of the wound. The steps are repeated similarly for the second end and second portion of the suture, starting with inserting the second end of the suture into the tissue of the second face of the wound below the surface adjacent the point of insertion of the first end.

[0025] An embodiment of a method is provided for joining a foreign element and bodily tissue, either of which may be referred to as first matter or second matter, using needles. The foreign element has a periphery and the bodily tissue has a fibrous tissue ring with a face of the fibrous tissue ring defining an opening and apposing a face of the periphery, and holding closed a junction between the element and the tissue. The first pointed end of the suture is inserted into the periphery of the foreign element at a point radially spaced from the face of the fibrous tissue ring. The first end of the suture is pushed through the periphery until the first end of the suture extends out of the periphery at an exit point and penetrates the tissue of a face of the fibrous tissue ring until the first end of the suture extends out of the tissue at an exit point radially spaced from the junction and spaced along the fibrous tissue ring circumference in a first direction from the point of insertion of the first end of the suture on the periphery. The first end of the suture is gripped and pulled, drawing the first portion of the suture through the periphery and the tissue while bringing the periphery and the tissue together to a closed position along the first portion of the suture. This continues until the second axial location is at the

point of insertion of the first end of the suture in the periphery and a length of the first portion of the suture is left in the periphery and the tissue between the point of insertion and the exit point. Then the first end of the suture is inserted into the tissue at the exit point of the first end. The first end is pushed through the tissue until the first end extends out of the tissue at an exit point in the face of the fibrous tissue ring and penetrates the periphery until the first end extends out of the periphery at an exit point radially spaced from the junction and spaced along the circumference of the fibrous tissue ring in the first direction from the immediately preceding point of insertion of the first end of the suture in the periphery. The first end of the suture is gripped and pulled out of the periphery, drawing the first portion of the suture through the periphery and tissue while bringing the periphery and the tissue together to a closed position along the first portion of the suture, and leaving a length of the first portion of the suture in the periphery between the point of insertion and the exit point. The above steps are repeated, with each repetition advancing the suture around the circumference of the junction in a first direction. Further, the above steps are repeated similarly for a second end and second portion of the suture, in a second direction. In addition, a similar method may be carried out with the suture first being inserted in the tissue rather than in the periphery of the foreign element. The sutures may extend completely around the circumference of the junction, and may overlap one quarter or more of the circumference. Yet another embodiment provides that the suture enter and exit tissue on the face of the junction, and not exit on the surface of the foreign element or the tissue. Examples of applications of these methods include placement of bioprosthetic heart valves, mechanical prosthetic heart valves, and bioprosthetics for cardiac septal defects.

[0026] Some embodiments include a method of mounting a device to bodily tissue, using needles. The device includes at least one eyelet for securing the device and through which a suture may pass. The method starts with the step of placing the device in a desired position. Then a suture is threaded through the eyelet. The first pointed end of the suture is inserted into tissue and is pushed through the tissue until extending out an exit point. The first end of the suture is gripped and pulled out of the tissue while drawing the first portion of the suture through the tissue, leaving a portion of the suture between the first and second axial locations out of the tissue and leaving a length of the first portion of the suture in the tissue between the point of insertion and exit point of the first end. These steps are repeated for the second end and portion of the suture in a second direction, resulting in the first and second portions of the suture extending in the tissue in generally opposing directions and causing the suture to resist displacement of the device. Examples of devices that may be mounted according to the present invention include catheters, electrodes of cardiac pacemakers, and tumor monitors. The device may be mounted internally, for example, to an organ, or externally to the epidermis.

[0027] Further, methods of performing cosmetic surgery are provided. One embodiment of a procedure using needles begins with inserting the first pointed end at an insertion point on the surface of a person's body. The first end of the suture is pushed through soft tissue until the first end extends out of the soft tissue at an exit point. The first end of the suture is gripped and pulled to draw the first portion of the

suture through the soft tissue until the second axial location is proximate to the point of insertion of the first end of the suture, leaving a length of the first portion of the suture in the soft tissue between the point of insertion and exit point of the first end. The second pointed end of the suture is put in place by repeating these steps for the second end and second portion. The soft tissue is manually grouped and advanced along at least one portion of the suture to provide the desired amount of lift.

[0028] Specific applications of cosmetic surgeries as described above include, for example, facelifts, browlifts, thigh lifts, and breast lifts. In an embodiment of a facelift, the insertion point is approximately at the temporal hairline, and the first end of the suture is pushed through subepidermal tissue to the exit point of on the scalp. The second end of the suture is pushed through subepidermal tissue, the superficial muscular aponeurotic system, or combinations thereof, to the exit point proximate to the nasolabial fold. Tissue is manually grouped and advanced along the second portion of the suture to provide the desired amount of lift.

[0029] In an embodiment of a browlift, the insertion point is on a person's face above the brow line. The first end of the suture is pushed through subepidermal tissue underneath the forehead, scalp, or both and the exit point of the first end of the suture is on the scalp. The second end of the suture is pushed through subepidermal tissue and the exit point of the second end of the suture is proximate to the brow. The tissue is manually grouped and advanced along the second portion of the suture to provide the desired amount of lift. The insertion may be approximately at the frontal hairline or the midpoint between the brow and frontal hairline.

[0030] Another embodiment of a browlift is provided for use with needles, and again the insertion point is on a person's face above the brow line. Examples of insertion point locations for browlifts include approximately at the frontal hairline or halfway between the brow and the frontal hairline. The first end of the suture is pushed through subepidermal tissue and the exit point of the first end of the suture is proximate to the brow. The second end of the suture is pushed through subepidermal tissue and the exit point of the second end of the suture is proximate to the brow and spaced from the exit point of the first end of the suture. Then the tissue is manually grouped and advanced along the first and second portions of the suture to provide the desired amount of lift.

[0031] An embodiment of a thigh lift is also provided. For a thigh lift, the insertion point is generally at the inguinal crease. The first end of the suture is pushed cranially through subepidermal tissue until the first end of the suture extends out of the tissue. The second end of the suture is pushed caudally through subepidermal tissue until the second end of the suture extends out of the tissue on the thigh, and then tissues are manually grouped and lifted as desired.

[0032] Further, a method of performing a cosmetic breast lift is provided. The insertion point is at the upper aspect of the breast curvature, and the first end of the suture is pushed through subcutaneous tissue, dermal tissue, and pectoralis muscle until extending out of the tissue at an exit point on the upper portion of the breast. The second end of the suture is pushed caudally through fibrous and fatty tissues until the second end of the suture extends out of the tissue at an exit

point along the anterior aspect or the lower curvature of the breast, and the tissue is manually grouped and lifted as desired.

[0033] Embodiments of cosmetic surgery using an insertion device are also provided. In these methods, the first pointed end of the suture and the leading end of the insertion device are inserted at an insertion point. The first end of the suture and the leading end of the insertion device are pushed through tissue beneath the epidermis until reaching an endpoint. Then the insertion device is gripped and pulled at the trailing end to remove the insertion device, leaving the suture in place, and the tissue is manually grouped and advanced along the first portion of the suture to provide the desired amount of lift. This method applies, for example, to a facelift, where the insertion point is in the scalp distal from the temporal hairline. The suture is pushed through the reticular dermis underneath the scalp, and the first end of the suture passes through the temporal hairline, penetrates the facial tissue such as the reticular dermis, the superficial muscular aponeurotic system, or a combination thereof, extending to the nasolobial fold. The method also applies to browlifts, where, for example, the insertion point is in the scalp at a point distal from the frontal hairline; and the suture is pushed through the reticular dermis underneath the scalp until the first end of the suture passes through the frontal hairline, extending to be proximate to the browline.

[0034] Other embodiments are provided for a method for joining and holding closed an axial wound in a blood vessel such as an artery or vein, using an insertion device. The first pointed end of the suture and the leading end of the insertion device are inserted through an entry point in the tissue spaced from and on one side of the wound. The first end of the suture and leading end of the insertion device are pushed through the tissue until penetrating the blood vessel wall on one side of the wound, continuing until extending into the interior of the blood vessel. The first end of the suture and leading end of the insertion device are then pushed through the interior of the blood vessel until the first end of the suture and the leading end of the insertion device penetrate the blood vessel wall on the other side of the wound, continuing through the blood vessel wall and penetrating the tissue on the other side of the wound. The first end of the suture and leading end of the insertion device are pushed through the tissue. In one embodiment, the second axial location is disposed in the blood vessel wall on one side of the wound and the first axial location is disposed in the blood vessel wall on the other side of the wound, resulting in no barbs being disposed in the interior of the blood vessel. The insertion device is gripped and pulled at the trailing end for removal, leaving the suture in place, and the tissue may be advanced on the two sides of the wound together as necessary to close the wound.

BRIEF DESCRIPTION OF THE DRAWINGS

[0035] For a more complete understanding of the present invention, reference should now be had to the embodiments shown in the accompanying drawings and described below. In the drawings:

[0036] FIG. 1 is a perspective view of an embodiment of a barbed suture with straight pointed ends for use according to the methods of the present invention;

[0037] FIG. 2 is a perspective view of a barbed suture with curved pointed ends for use according to the methods of the present invention;

[0038] FIGS. 3-6 are plan views of an embodiment of a method according to the present invention for joining two sides of an open wound in tissue;

[0039] FIGS. 7-10 are perspective views of another embodiment of a method according to the present invention for joining two sides of an open wound in tissue;

[0040] FIG. 11 is a perspective view of a prior art method for joining two sides of an open wound in tissue using a spiraling suture path;

[0055] FIGS. 43-44 are partially sectioned perspective views of an embodiment of the method according to the present invention for closure of ulcerative intestinal lesions or other bowel wall defects;

[0056] FIG. 45-46 are front elevation views of two embodiments of the method according to the present invention for closure of a cystostomy incision in the urinary bladder;

[0057] FIG. 47 is a front elevation view of an embodiment of the method according to the present invention for securing prosthetic heart valves;

[0058] FIG. 48 is a front elevation view of an embodiment of the method according to the present invention for securing a catheter in position;

[0059] FIG. 49 is a perspective view of embodiments of the method according to the present invention for performing cosmetic surgery;

[0060] FIGS. 50-52 are cross-section views of an axial wound closure in a blood vessel according to two embodiments of the present invention.

DESCRIPTION

[0061] As used herein, the term "wound" means a surgical incision, cut, laceration, severed tissue or accidental wound in human skin or other bodily tissue, or other condition where suturing, stapling, or the use of another tissue connecting device might be required.

[0062] As used herein, the term "tissue" includes tissues such as skin, bone, muscle, organs, and other soft tissue such as tendons, ligaments and muscle.

[0063] Certain other terminology is used herein for convenience only and is not to be taken as a limitation on the invention. For example, words such as "upper," "lower," "left," "right," "horizontal," "vertical," "upward," and "downward" merely describe the configuration shown in the figures. It is understood that the components may be oriented in any direction and the terminology, therefore, should be understood as encompassing such variations unless specified otherwise.

[0064] Referring now to the drawings, wherein like reference numerals designate corresponding or similar elements throughout the several views, there is shown in FIGS. 1 and 2 a suture for use according to the present invention and generally designated at 40. The suture 40 includes an elongated body 42 having a plurality of barbs 44 disposed along the length of the body 42. First and second ends 46, 48 of the body 42 terminate in points 50, 52 for penetrating tissue.

[0065] The body 42 of the suture 40 is, in one embodiment, circular in cross section. Suitable diameters for the body 42 of the suture 40 range from about 0.001 mm to about 1.0 mm. The body 42 of the suture 40 could also have a non-circular cross-sectional shape which would increase the surface area of the body 42 and facilitate the formation of multiple barbs 44.

[0066] The length of the suture 40 can vary depending on several factors such as the extent of the wound to be closed, the type of tissue to be joined, the location of the wound, and

the like. A suture 40 of proper length is selected for achieving suitable results in a particular application.

[0067] Material for the body 42 of the suture 40 is available in a wide variety of monofilament suture material. The particular suture material chosen depends on the strength and flexibility requirements. In one embodiment, the material for the body 42 is flexible and substantially nonresilient so that the shape of an inserted suture 40 will be determined by the path of insertion and the surrounding tissue. In some applications, however, it may be desirable for at least a portion of the body 42 to have sufficient dimensional stability to assume a substantially rigid configuration during use and sufficient resiliency to return to a predetermined position after deflection therefrom. The portions of the ends 46, 48 of the suture 40 adjacent the points 50, 52 may be formed of a material sufficiently stiff to enable the points 50, 52 to penetrate tissue in which the suture 40 is used when a substantially axial force is applied to the body 42. Variations in surface texture of the body 42 of the suture 40 can impart different interaction characteristics with tissues.

[0068] The body 42 can be formed of a bioabsorbable material which allows the suture 40 to be absorbed over time into the tissue as the wound heals. Bioabsorbable material is particularly useful in arthroscopic surgery and methods of suturing. Many compositions useful as bioabsorbable materials can be used to make the body 42 of the suture 40 for use in the methods of the present invention. Generally, bioabsorbable materials are thermoplastic polymers. Selection of the particular material is determined by the desired absorption or degradation time period which depends upon the anticipated healing time for the subject of the procedure. Biodegradable polymers and co-polymers range in degradation time from about one month to over twenty-four months. They include, but are not limited to, polydioxanone, polylactide, polyglycolide, polycaprolactone, and copolymers thereof. Other copolymers with trimethylene carbonate can also be used. Examples are PDS II (polydioxanone), Maxon (copolymer of 67% glycolide and 33% trimethylene carbonate), and Monocryl (copolymer of 75% glycolide and 25% caprolactone). Germicides can also be incorporated into the body 42 of the suture 40 which are retained by the suture 40 to provide long lasting germicidal properties.

[0069] The body 42 of the suture 40 can also be formed from non-absorbable material such as nylon, polyethylene terephthalate (polyester), polypropylene, and expanded polytetrafluoroethylene (ePTFE). Alternatively, the suture body 42 can also be formed of metal (e.g. steel), metal alloys, plastic, or the like.

[0070] The plurality of barbs 44 is axially-spaced along the body 42 of the suture 40. The barbs 44 are oriented in one direction facing toward the first end 46 of the suture 40 for a first portion 54 of the length of the suture and in an opposite direction facing the second end 48 of the suture 40 for a second portion 56 of the suture. The barbs 44 are yieldable toward the body 42. The barbs 44 on each portion 54, 56 of the suture are oriented so as to allow movement of the suture 40 through the tissue in one direction along with the corresponding end 46, 48 of the suture 40. The barbs 44 are generally rigid in an opposite direction to prevent the suture 40 from moving in the tissue in the opposite direction.

[0071] The barbs 44 can be arranged in any suitable pattern, for example, in a helical pattern as shown in FIGS.

1 and 2. The number, configuration, spacing and surface area of the barbs **44** can vary depending upon the tissue in which the suture **40** is used, and depending on the composition and geometry of the suture body. The proportions of the barbs **44** may remain relatively constant while the overall length of the barbs **44** and the spacing of the barbs **44** are determined by the tissue being connected. For example, if the suture **40** is intended to be used to connect the edges of a wound in skin or tendon, the barbs **44** can be made relatively short and more rigid to facilitate entry into this rather firm tissue. If the suture **40** is intended for use in fatty tissue, which is relatively soft, the barbs **44** can be made longer and spaced farther apart to increase the holding ability in the soft tissue. Moreover, the ratio of the number of barbs **44** on the first portion **54** of the suture **40** to the number of barbs **44** on the second portion **56**, and the lengths of each portion **54**, **56**, can vary depending on the application and needs.

[0072] The surface area of the barbs **44** can also vary. For example, fuller-tipped barbs **44** can be made of varying sizes designed for specific surgical applications. For joining fat and relatively soft tissues, larger barbs **44** are desired, whereas smaller barbs **44** are more suited for collagen-dense tissues. There are also situations where a combination of large and small barbs **44** within the same structure will be beneficial such as when a suture **40** is used in tissue repair with differing layer structures. Use of the combination of large and small barbs **44** with the same suture **40** wherein barb **44** sizes are customized for each tissue layer will ensure maximum anchoring properties.

[0073] The barbs **44** may be formed on the surface of the body **42** according to any suitable method, including cutting, molding, and the like. The preferred method is cutting with acute angular cuts directly into the suture body **42** with cut portions pushed outwardly and separated from the body **42** of the suture **40**. The depth of the barbs **44** formed in the suture body **42** depends on the diameter of the suture material and the depth of cut. A particularly suitable device for cutting a plurality of axially spaced barbs **44** on the exterior of suture filaments utilizes a cutting bed, a cutting bed vise, a cutting template, and a blade assembly to perform the cutting. When operated, the cutting device has the ability to produce a plurality of axially spaced barbs **44** in the same or random configuration and at different angles in relation to each other. Various other suitable methods of cutting the barbs **44** have been proposed including the use of a laser. The barbs **44** could also be cut manually. However, manually cutting the barbs **44** is labor intensive, decreases consistency, and is not cost effective. The suture **40** could also be formed by injection molding, extrusion, stamping and the like. The suture **40** can be packaged in any number of desired pre-cut lengths and in pre-shaped curves.

[0074] The ends **46**, **48** of the suture **40** may be straight (**FIG. 1**) or curved (**FIG. 2**). In one embodiment, the ends **46**, **48** of the suture **40** may be surgical needles secured at each end of the body **42** of the suture **40** so that the body **42** extends between the shank ends of the two needles. The needles are preferably constructed of stainless steel or other surgical grade metal alloy. The needles may be secured to the suture body **42** by means of adhesives, crimping, swaging, or the like, or the joint may be formed by heat shrinkable tubing. A detachable connection may also be employed such that the needles may be removed from the body **42** of the

suture **40** by a sharp tug or pull or by cutting. The length of the needles is selected to serve the type of tissue being repaired so that the needles can be completely removed leaving the suture body **42** in the desired position within the tissue.

[0075] Barbed sutures suitable for use according to the methods of the present invention are described in U.S. Pat. No. 5,342,376, entitled "Inserting Device for a Barbed Tissue Connector", U.S. Pat. No. 6,241,747, entitled "Barbed Bodily Tissue Connector", and U.S. Pat. No. 5,931,855. The contents of U.S. Pat. No. 5,342,376, U.S. Pat. No. 6,241,747, and U.S. Pat. No. 5,931,855 are hereby incorporated by reference.

[0076] According to the present invention, a surgical procedure using barbed sutures **40** is provided for binding together living tissue for healing and regrowth or reconfiguration in vivo. In general, when the suture **40** is used in tissue to repair a wound, the suture is passed through tissue at each of the sides of the wound. The point **50** at one end **46** of the suture **40** is inserted into a first side of a wound such that the point **50** pierces the tissue and the barbs **44** on the end portion **54** of the suture **40** corresponding to the one end **46** yield toward the body **42** to facilitate movement of the suture **40** through the tissue in the direction of insertion. The other end **48** of the suture **40** is also inserted into a side of the wound and advanced through the tissue in like manner. The sides or faces of the wound are then moved together along the suture portions **54**, **56** within the tissue to close the wound. The barbs **44** of the suture **40** grasp the surrounding tissue on each side of the wound and maintains the edges of the wound in position during healing. The leading ends **46**, **48** of the suture **40** protruding from the tissue are then cut and discarded. In one embodiment, ends of the suture **40** in the tissue are made to lie below the surface of the skin by first depressing the skin immediately around the ends and severing the suture body **42** closely against the skin. The skin will rise to cover the ends of the suture **40**.

[0077] **FIGS. 3-6** show a section of tissue including a portion of a patient's skin **58** and subcutaneous tissue defining a wound **60** from the surface of the skin **58** down into the tissue. It is understood that the wound **60** in the tissue can be of any configuration and from any anatomical part or organ of the body. Accordingly, depending on the configuration of the wound, the wound may comprise several sides and faces. However, the wounds depicted in the figures are straight incisions in the skin **58** to reduce the complexity of the description of the method of the present invention. It is understood that the applicants do not intend to limit the method of the present invention to the closure of only straight incisions.

[0078] In this embodiment of the method of the present invention, the user, such as a surgeon, selects a suture **40** of sufficient length and having straight ends **46**, **48**. As noted above, in one embodiment, the ends **46**, **48** may be surgical needles.

[0079] Referring to **FIG. 3**, the surgeon inserts the needle **46** at the end of the first portion **54** of the suture **40** into the tissue at a point **62** on a first side **64** of the wound **60** and laterally spaced from the face **66** of the wound **60** at the first side **64**. The surgeon advances the needle **46** along a selected substantially straight path through the tissue to extend out of the tissue at a subcutaneous point (not shown) in the first

face 66 of the wound 60 and subcutaneously penetrating a point (not shown) in a face 68 of a second side 70 of the wound 60. The surgeon continues to advance the needle 46 through the tissue until the point 50 of the needle emerges from the tissue at a distal end of the selected path at an exit point 72 on the second side 70 of the wound 60. The exit point is laterally spaced from the face 68 of the second side 70 of the wound and longitudinally spaced in a first direction from the point of insertion 62 at the first side 64 of the wound 60. The surgeon grips the exposed portion of the needle 46 and pulls the needle 46 out of the tissue. This action draws the first portion 54 of the suture 40 having barbs 44 for resisting movement in the opposite direction through the tissue until the barbs 44 on the second portion 56 engage the surface of the skin 58 at the insertion point 62 preventing further advancement of the suture 40 through the tissue. A length of the first portion 54 of the suture body 42 is thus positioned in the tissue along the selected path. The faces 66, 68 of the wound 60 are approximated by pushing the adjacent sides 64, 70 of the tissue together along the first portion 54 of the body 42 of the suture 40 in the tissue.

[0080] The needle 46 is next inserted into the tissue at the exit point 72 and advanced along a substantially straight path through the tissue to extend out of the tissue at a subcutaneous point 74 in the second face 68 of the wound 60 and subcutaneously penetrating a point 76 in the first face 66 of the wound 60. The surgeon continues to advance the needle 46 through the tissue until the point end 50 emerges from the tissue at a distal end of the selected path at an exit point 78 on the first side 64 of the wound 60 that is laterally spaced from the first face 66 and longitudinally spaced in the first direction from the point of insertion 72 at the second side 70 of the wound 60. Again the surgeon grips the exposed portion of the needle 46 and pulls the needle 46 out of the tissue, drawing the first portion 54 of the suture 40 through the tissue.

[0081] The previous steps are repeated with the first portion 54 of the suture 40 by inserting the needle 46 into the exit point 78 on the first side 64 of the wound 60 for advancing longitudinally in the first direction along the wound 60 in a "zigzag" pattern as shown in FIG. 4. The number of passes of the needle 46 is chosen in accordance with the size of the wound 60 and the strength required to hold the wound closed. The remaining length of the first portion 54 of the suture 40 protruding from the tissue at a first end 80 of the wound 60 is cut and discarded, leaving the remaining first portion 54 of the suture 40 in the tissue. The faces 66, 68 of the wound 60 are approximated by pushing the adjacent sides 64, 70 of the tissue together along the body 42 of the suture 40 in the tissue.

[0082] It is understood that the step of approximating the sides 64, 70 of the wound 60 can be performed as the suture 40 is advanced or after the end 80 of the wound 60 is reached. Moreover, we do not intend to limit ourselves to the depth of the suture paths shown in the FIGs. as the depth of the suture paths may be determined by the surgeon or the wound to be closed. Further, it is understood that straight ends 46, 48 of the suture may also produce more curved transitions as determined by the surgeon.

[0083] The surgeon repeats the steps of this procedure with the second needle 48 on the second portion 56 of the suture (FIG. 5). The initial insertion point 62 of the second

needle 48 is at the same initial point of insertion 62 of the first needle 46 at the first side 64 of the wound 60. The surgeon thus advances the second portion 56 of the suture 40 into the tissue along the wound 60 in a direction toward the other end 82 of the wound 60 using the same zigzag pattern approximating the faces 66, 68 of the wound 60. The remaining length of the second portion 56 of the suture 40 protruding from the skin 58 at the end 82 of the wound 60 is then cut and discarded (FIG. 6).

[0084] An embodiment of the method for joining the sides of an open wound in tissue according to the present invention using a subcuticular stitch is shown in FIGS. 7-10. The tissue shown in the figures includes an epidermis 84, dermis 86, fat 88, fascia 90 and muscle 92. By penetrating the subcutaneous layers only and not the outer skin 58 layer, a wound 60 can be closed to facilitate healing while minimizing scar tissue.

[0085] Referring to FIG. 7, the subcuticular stitch method of the present invention uses a barbed suture 40 including curved ends 46, 48. The surgeon begins by inserting the first needle 46 into the tissue below the skin 58 surface at a face 66 on a first side 64 of the wound 60 at an initial insertion point 63 longitudinally spaced from the ends 80, 82 of the wound 60. The surgeon advances the needle 46 through the tissue along a curvilinear path until the point 50 of the needle 46 extends from the tissue at a subcutaneous exit point 73 in the first face 66 of the wound 60 longitudinally spaced toward one end 80 of the wound from the entry point 63 of the needle 46. The surgeon grips the needle 46 and pulls the needle 46 out of the tissue, drawing the first portion 54 of the suture 40 through the tissue until the barbs 44 on the second portion 56 engage the tissue at the insertion point 63 preventing further advancement of the suture 40 through the tissue. A length of the first portion 54 of the suture body 42 is thus positioned in the tissue along the selected curvilinear path as seen in FIG. 7.

[0086] Turning to FIG. 8, the surgeon then inserts the needle 46 into the tissue at a subcutaneous entry point (not shown) in the face 68 at the second side 70 of the wound 60. The surgeon repeats the above steps of pushing the needle 46 through the tissue along a selected curvilinear path so that the point 50 of the needle 46 emerges from a subcutaneous exit point (not shown) in the second face 68 of the wound 60 longitudinally spaced toward the end 80 of the wound 60 from the entry point. The surgeon grips the needle 46 and draws the first portion 54 of the suture 40 into the tissue further along the wound 60. In this manner, the surgeon advances the first portion 54 of the suture 40 longitudinally along the wound 60 to the one end 80 of the wound in a wave-like or "sinusoidal" pattern. As noted above, the faces 66, 68 of the wound 60 are approximated as the surgeon progresses, or when the end 80 of the wound 60 is reached, by pushing the adjacent sides 64, 70 of the tissue together along the body 42 of the suture 40. The needle 46 along with remaining length of the first portion 54 of the suture 40 is drawn through the surface of the skin 58 at the one end 80 of the wound 60 is cut and discarded (FIG. 8).

[0087] The surgeon repeats the procedure at the other end of the wound (FIG. 9) with the second portion 56 of the suture 40. The surgeon begins by inserting the second needle 48 into the tissue at a subcutaneous point (not shown) in the second face 68 of the wound 60. The surgeon advances the

second needle 48 along a curvilinear path from the point of initial insertion toward the other end 82 of the wound 60 until the needle 48 emerges from a subcutaneous exit point (not shown) the second face 68 of the wound 60 longitudinally spaced from the initial entry point of the needle 48. The surgeon then pulls the needle 48 from the tissue, drawing the second portion 56 of the suture 40 into the tissue, and inserts the needle 48 into the first face 66 of the wound 60 at a subcutaneous entry point (not shown) at the first side 64 of the wound 60. Again, the surgeon advances the needle 48 along a curvilinear path until the needle 48 emerges from a subcutaneous exit point 98 in the face 66 further toward the other end 82 of the wound and draws the needle 48 and suture portion 56 through the tissue. FIG. 9 shows the needle 48 being drawn a second time from the second face 68 of the wound 60. Thus, the surgeon advances the second portion 56 of the suture in a sinusoidal pattern to the end 82 of the wound 60 (FIG. 10) and approximates the faces 66, 68 of the wound 60. The length of the second portion 56 of the suture body 42 protruding from the skin 58 at the end of the wound 60 is then cut and discarded.

[0088] FIG. 11 shows a prior art subcutaneous suturing method for closing a wound 60 using a spiraling, “corkscrew-shaped” stitch pattern. The surgeon begins at one end 80 of the wound by tying a knot 100 in the first loop and advancing the suture in a corkscrew pattern to the other end of the wound 82 where the suture is tied off. Tying the knots at the end and burying them, which is preferred by the surgeon, is technically very challenging, even more so when the incision is almost closed.

[0089] FIGS. 12-15 show a similar corkscrew-shaped stitch pattern for closing a wound 60 according to an embodiment of the method of the present invention. This embodiment is similar to the method described above using a subcutaneous sinusoidal stitch pattern.

[0090] Referring to FIG. 12, the surgeon begins by inserting one of the needles 46 into the tissue below the skin 58 surface at a face 66 on a first side 64 of the wound 60 at an initial subcutaneous insertion point 63 longitudinally spaced from the ends 80, 82 of the wound 60. The surgeon advances the needle 46 upward through the tissue along a curvilinear path until the point 50 of the needle 46 extends from the tissue at a subcutaneous exit point 73 in the first face 66 of the wound 60 longitudinally spaced toward one end 80 of the wound and above the entry point 63 of the needle 46. The surgeon then inserts the needle 46 into the tissue at a subcutaneous entry point 102 in the face 68 at the second side 70 of the wound 60. The surgeon pushes the needle 46 through the tissue along a selected curvilinear path so that the point 50 of the needle 46 emerges from a subcutaneous exit point 104 in the second face 68 of the wound 60 longitudinally spaced toward the end 80 of the wound 60 and below the entry point 102. The surgeon repeats these steps (FIG. 13) for advancing the first portion 54 of the suture 40 longitudinally along the wound 60 to the one end 80 of the wound in the spiraling, corkscrew stitch pattern. It is understood that the number and diameter of coils can be varied as desired. At any selected convenient point, the surgeon grips the needle 46 for drawing the first portion 54 of the suture 40 through the tissue until the barbs 44 on the second portion 56 engage the tissue at the insertion point 63 preventing further advancement of the suture 40 through the tissue. The surgeon approximates the faces 66, 68 of the wound 60 as

the surgeon progresses or when the end 80 of the wound 60 is reached as described above. The remaining length of the first portion 54 of the suture 40 is drawn through the surface of the skin 58 at the one end 80 of the wound 60 and cut and discarded.

[0091] The surgeon repeats the procedure at the other end 82 of the wound 60 with the second portion 56 of the suture 40. As seen in FIG. 14, several “coils” of the second portion 56 of the suture 40 have been entered into the tissue in a direction toward the other end 82 of the wound 60. Subcutaneous entry points 106 and exit points 108 in the faces 66, 68 of the wound 60 are visible. The surgeon advances the second portion 56 of the suture 40 to the end 82 of the wound 60 (FIG. 15) and approximates the faces 66, 68 of the wound 60. The length of the second portion 56 of the suture body 42 protruding from the skin 58 at the end of the wound 60 is then cut and discarded.

[0092] Another embodiment of a subcutaneous suturing method for joining and holding closed an open wound 60 in tissue according to the present invention is shown in FIGS. 16-18. This method also uses a barbed suture 40 having curved pointed ends 46, 48, such as surgical needles.

[0093] Referring to FIG. 16, the surgeon begins by inserting the first needle 46 subcutaneously into the tissue at a face 66 on a first side 64 of the wound 60 at an initial insertion point 63 adjacent one end 80 of the wound 60 and pushes the needle 46 through the tissue along a selected curvilinear path until the needle 46 extends from the tissue at a subcutaneous exit point 73 in the first face 66 of the wound 60 longitudinally spaced from the end 80 of the wound 60 in a direction toward the other end 82 of the wound 60. The surgeon grips the needle 46 and pulls the needle 46 out of the tissue for drawing the first portion 54 of the suture 40 including barbs 44 for resisting movement in the opposite direction through the tissue until the barbs 44 of the second portion 56 engage the first face 66 of the wound 60 at the insertion point 63 preventing further advancement of the suture 40 into the tissue. A length of the first portion 54 of the suture body 42 is thus positioned in the tissue along the selected curvilinear path.

[0094] As further seen in FIG. 16, the surgeon next inserts the second surgical needle 48 into the tissue at a subcutaneous entry point (not shown) in the face 68 at the second side 70 of the wound 60 substantially opposite the initial point of insertion 63 of the first needle 46 at the one end 80 of the wound 60. The surgeon advances the second needle 48 through the tissue along a selected curvilinear path until the needle 48 extends from the tissue at a subcutaneous exit point (not shown) in the second face 68 of the wound 60. The surgeon then pulls the second needle 48 for drawing the second portion 56 of the suture 40 through the tissue, including barbs 44 for resisting movement in the opposite direction, leaving a length of the second portion 56 of the suture 40 in the tissue at the end 80 of the wound 60.

[0095] The surgeon repeats the above steps with the first needle 46 and second needle 48 at the second and first sides 64, 70, respectively, of the wound 60. In this manner, the surgeon advances the suture 40 longitudinally along the wound 60 from the one end 80 of the wound to the other 82 in a “shoelace” pattern. As seen in FIG. 17, several passes of the suture 40 have been entered into the tissue of the wound 60. The faces 66, 68 of the wound 60 are approxi-

mated as the surgeon progresses, or when the end **82** of the wound **60** is reached, by pushing the adjacent sides **64**, **70** of the tissue together along the body **42** of the suture **40**. The lengths of the first portion **54** and second portion **56** of the suture **40** protruding from the skin **58** are cut and discarded (**FIG. 18**).

[0096] It is understood that the method of the present invention shown in **FIGS. 7-10** can be used to generate a similar stitch pattern if a second suture is used which is entered in the tissue to mirror the path of the first suture.

[0097] Another embodiment of the method according to the present invention for joining the sides **64**, **70** of tissue in an open wound **60** is shown in **FIGS. 19 and 20**. In this embodiment, the surgeon inserts a first curved or straight end **46** of the suture **40**, such as a needle, into the tissue at a point **62** on a first side **64** of the wound **60** and laterally spaced from the face **66** of the wound **60** at the first side **64**. The surgeon advances the needle **46** through the tissue along a curvilinear path until the needle **46** emerges from the tissue on a second side **70** of the wound at an exit point **72** laterally spaced from the face **68** of the second side **70** of the wound **60** and longitudinally spaced in a first direction from the point of insertion **62**. This path subcutaneously passes through both faces **66**, **68** of the wound **60**. The surgeon grips the needle **46** and pulls the needle **46** out of the tissue for drawing the first portion **56** of the suture **40** through the tissue until the barbs **44** of the second portion **56** engage the surface of the skin **58** at the insertion point **62** preventing further advancement of the suture **40** into the tissue. The faces **66**, **68** of the wound **60** are approximated by pushing the adjacent sides **64**, **70** of the tissue together along the body **42** of the suture **40** in the tissue. The length of the first portion **54** of the body **42** of the suture **40** protruding from the skin **58** is cut and discarded (**FIG. 19**).

[0098] The surgeon then inserts the second needle **48** into the tissue at the point of insertion **62** of the first needle **46** at the first side **64** of the wound **60**. The surgeon pushes the needle **48** through the tissue along a curvilinear path which substantially mirrors the passage of the first needle **46** until the needle **48** emerges from the tissue at an exit point **110** laterally spaced from the wound and longitudinally spaced in a second direction from the point of insertion **62** such that the paths of the first and second portions **54**, **56** of the suture **40** overlap. Again, the path of the second needle **48** subcutaneously passes through the faces **66**, **68** of the wound **60**. The surgeon grips the second needle **48** and pulls the needle **48** from the tissue for drawing the second portion **56** of the suture **40** into the tissue. The length of the second portion **56** of the suture **40** protruding from the skin **58** is cut and discarded, leaving a stitch in the tissue which resembles the Greek letter alpha (**FIG. 20**).

[0099] This stitch has its greatest benefit in small wound and incision closure. The alpha-shaped stitch can be placed quickly in tissue as compared with conventional loop sutures. Moreover, this stitch pattern has no blood constricting loops, leaves no stitch marks on the surface of the skin, and does not have to be removed from the patient if bio-absorbable material is used. Two or more of the alpha-shaped stitches may be used to close a larger wound.

[0100] A particular application of the alpha-stitch according to the method of the present invention is as a means of restricting bleeding from an arterial opening by constricting

the tissue above and around the arterial opening. For example, the introduction and removal of catheters into the femoral artery is typically required when performing cardiac catheterization, percutaneous interventions, and other vascular procedures. These puncture wounds are typically self-sealing after several hours of sustained external pressure at and around the insertion site of the puncture wound. **FIGS. 21 and 22** show the alpha-stitch according to a method of the present invention positioned for performing this function. Note that the path of the suture portions **54**, **56** is curvilinear with the respect to the skin **58** surface and that the deepest points of the arcs pass immediately above the puncture site **112** in the artery **114**. In this embodiment, the ends **46**, **48** of the suture **40** are pulled to put tension in the tissue. As the ends **46**, **48** of the suture **40** are pulled, the tissue embraced by the suture is pulled both inward from the areas lateral to the artery **114** and downward from areas immediately above the artery **114**. This constriction of tissue increases the density of tissue around the arterial puncture site **112** and imparts forces with vectors directed toward the arteriotomy site to limit bleeding. Further, this suture method avoids the need to traverse the artery wall or lumen, thus eliminating the risk of vessel wall dissection and promoting introgenic thrombogenesis.

[0101] The method of the present invention is also useful in binding together partially or completely severed tendons or other internal tissue repairs requiring considerable tensile strength. For example, referring to **FIG. 23**, a finger **120** is shown with a portion of the outer layer of tissue cut-away to schematically show a severed tendon **122**. A Kessler suturing method for joining the two ends **124**, **126** of the tendon **122** is shown in **FIG. 24**. This method requires the surgeon to apply an intricate stitch pattern and to complete the tendon connection with one or two technically challenging knots **128**. No portion of the suture knot **128** may protrude from the outside surface of the repaired tendon **122** where it could snag the surrounding tendon sheath and impede healing. The knot **128** also presents a particular dilemma since it must be tied between the two ends **124**, **126** of the tendon **122**, where it can be a barrier between tendon sections that must appose in order to effectively heal. A further limitation of the conventional tendon repair method is that relatively small amounts of tension can stretch the tendon **122**, allowing it to slide along the smooth monofilament fiber and effectively disrupt, or in the case of greater amounts of tension, separate completely at the wound margin. This outcome substantially limits healing even though the suture material remains intact.

[0102] A method according to the present invention for joining the two ends **124**, **126** of the tendon **122** is shown in **FIGS. 25-28**. Referring to **FIG. 25**, the surgeon begins by inserting the first end **46** of the suture **40**, which may be a straight or curved surgical needle, into one end **124** of the tendon **122** and pushing the needle **46** through the tendon **122** along a selected curvilinear path until the point **50** of the needle **46** extends from an exit point **130** in the periphery of the tendon **122** longitudinally spaced from the one end of the tendon **122**. The first needle **46** is gripped and pulled out of the tendon for drawing the first portion **54** of the suture **40** through the tendon **122** leaving a length of the first portion **54** of the suture in the tendon end **124** between the end of the tendon **122** and the exit point **130**. The surgeon reinserts the needle **46** into the periphery of the tendon **122** at an entry point **132** immediately adjacent the exit point **130** and

pushes the needle 46 along a selected curvilinear path until the point 50 of the needle 46 exits the other side of the tendon at an exit point 134 that is longitudinally spaced from the entry point 132. It is understood that the surgeon could use the exit point 130 as the next entry point for the needle 46 if desired. The surgeon pulls the needle 46 out of the tendon for drawing the first portion 54 of the suture 40 through the tendon 122, reinserts the needle 46 into the side of the tendon 122 at an entry point 136 immediately adjacent the exit point 134 and pushes the needle 46 along a selected curvilinear path back out of the other side of the tendon 122 at an exit point 138 longitudinally spaced from the previous entry point 136. It is understood that the surgeon makes as many passes as deemed necessary for holding the end 124 of the tendon 122, or as the length or thickness of the tendon 122 allows, and removes the remaining length of the first portion 54 of the suture 40.

[0103] As seen in FIG. 26, these steps are repeated with the second portion 56 of the suture 40 at the other end 126 of the tendon 122. The pattern of the second portion 56 of the suture 40 in the second end 126 of the tendon 122 generally mirrors the first portion 54 of the suture 40 in the first end 124 of the tendon 122, including exit points 130a, 134a, 138a and entry points 132a, 136a. The ends 124, 126 of the tendon 122 are brought together while maintaining tension on the free ends of the sutures.

[0104] Referring now to FIG. 27, a second suture 40a is introduced at the second end 126 of the tendon 122. The first needle 46a of the second suture 40a is inserted into the end 126 of the tendon 122 and pushed through the tendon 122 along a selected curvilinear path until the needle 46a extends from an exit point 140 in the periphery of the tendon 122 substantially opposite the first exit point 130a of the second portion 56 of the first suture 40. The needle 46a of the second suture 40a is pulled out of the tendon 122 for drawing the first portion 54a of the second suture 40a through the tendon 122 leaving a length of the suture 40a in the tendon 122 between the end 126 of the tendon 122 and the exit point 140. The surgeon repeats the steps described above by reinserting the needle 46a into the tendon 122 at an entry point 142 (FIG. 28) adjacent the exit point 140 and pushing the needle 46a along a selected curvilinear path until the needle 46a emerges from an exit point 144 in the periphery of the tendon 122 substantially opposite the second exit point 134a of the second portion 56 of the first suture 40. In this manner, the surgeon advances longitudinally along the end 126 of the tendon 122 entering at 146 and exiting at 148. The previous steps are repeated at the other end 124 of the tendon 122 with the second portion 56a of the second suture 40a. The number of sutures used depends on the size, caliber, and length of the tendon to be repaired. Big tendons will require more than two sutures whereas one may suffice for very small tendons.

[0105] Tendon repair with two sutures according to the present invention exhibits equivalent or better holding power as the prior art technique. Moreover, tendons repaired according to the methods of the present invention maintain their original configuration, profile, contour, and form better when being stretched.

[0106] The method of the present invention may be embodied in many surgical procedures. The procedures include both "open" surgery as well as endoscopic and

laparoscopic surgery. Further, the uses of embodiments of the present invention may include repair of wounds, fastening of tissue junctions formed by the procedures, and positioning of tissue. The surgical procedures described herein are known to those of ordinary skill in the art, and accordingly are described only to a level of detail required to convey the respective embodiments of the method of the present invention. In FIGS. 29-48, where various steps of insertion are omitted from a drawing, it should be understood that the description and accompanying text of FIGS. 1-28 apply to inserting the sutures 40.

[0107] FIG. 29 shows a stomach 200 prior to performance of a Nissen fundoplication. This procedure is performed on patients who suffer from gastroesophageal reflux disease and do not respond to medical treatment. As shown, the first portions 54 of two respective barbed sutures 40 are inserted into a proximal location of the fundus 202 and into the serosal and muscularis layers, and the respective second portions 56 remain free. The stomach's fundus 202 is pulled behind and wrapped 206 around the esophagus 204. The respective second portions 56 are then advanced similarly into the apposing part 208 of the stomach 200, as shown in FIG. 30.

[0108] The same result in fastening may be achieved by performing the procedure in a different order. The fundus 202 may be pulled and wrapped 206 behind the esophagus 204 first, and then temporarily clamped or stapled in place while the first and second portions 54, 56 are inserted in the configuration shown in FIG. 30. Other sequences may also be used and remain within the scope of the present invention.

[0109] The barbed suture 40 may also be inserted as shown in FIG. 31, in either a sinusoidal or coiled configuration as previously described. The curved insertion is performed subsequent to pulling and wrapping 206 the fundus 202 behind the esophagus 204, and then clamping or stapling in place.

[0110] FIG. 32 shows a laparoscopic insertion device 220 used to stabilize a bowel structure 222 in position in advance of performing an anastomosis, whereby an end-to-end surgical connection of hollow organs is conventionally performed. The laparoscopic insertion device 220 comprises a tubular body in which the barbed suture 50 is disposed, with holes at the leading and trailing ends, similar to that disclosed in U.S. Pat. No. 5,342,376 to Ruff, the contents of which were previously incorporated by reference herein. The insertion device 220 penetrates using the point 50 of the suture to pierce the epidermis 84, dermis 86, fat 88, fascia 90, muscle 92, and the peritoneum 94 before passing into the abdominal cavity 224. The insertion device 220 then passes into the bowel structure 222. A laparoscopic grasping tool 226 is shown to be holding the bowel structure in position until the suture is in place. It should be noted that the bowel structure 222 may also be stabilized by placement of a barbed suture 40 from the inside of the structure 222.

[0111] In FIG. 33, the laparoscopic insertion device is removed by pulling it outward 228, exposing the suture 40, while the pointed end 50 of the suture 40 is retained by its barbs against the removal force of the insertion device 220. The suture 40 is in place in FIG. 34. When the procedure that gave rise to the need to tie the bowel structure 222 in place is complete, the suture may be cut at an exposed point

229. As shown, the trailing end of the suture **40** extends through the epidermis **84** at the point of initial insertion, and the suture **40** may be cut at point **229** to allow that portion of the suture **40** to be removed by pulling on the trailing end.

[0112] Optionally, the barbed suture pointed end **50** may continue through the bowel structure **222** tissue, into the abdominal cavity **224**, and through any number of desired selected layers of the peritoneum **94**, muscle **92**, fascia **90**, fat **88**, dermis **86**, and epidermis **84**. If the suture **40** passes through the epidermis **84** and is to be left in place, the suture **40** may be cut off such that the end of the suture **40** resides beneath the epidermis **84**. Alternatively, in a method similar to that described for **FIG. 34**, when the procedure that gave rise to the need to tie the bowel structure **222** in place is complete, the suture **40** may be cut at the exposed point **229** and in addition at another exposed point along the suture **40** on the opposite side of the bowel structure **222**, allowing removal of both ends of the suture **40**.

[0113] A portion of the biliary system is shown in **FIG. 35**. The liver **230** is shown in partial section view, and the gallbladder **232**, bowel **234**, and stomach **200** are the other organs that are shown. The barbed suture of the present invention may be used to perform a Rodney Smith procedure with Roux-en-Y for the anastomosis of the bowel **234** to the liver **230**. In such an operation, the bile duct **236** may be cut, for example, at point **237** and anastomized to the bowel **234** at an incision in the bowel **234** at point **238**. The sutures **40** may be inserted as shown in **FIG. 36** with either an insertion device or with needles as previously discussed. The remaining portion of the bile duct **239** is removed and the wound at the end where it connects to the bowel **234** is sutured closed, which may also be done with sutures **40** of the present invention. In addition, barbed sutures can be placed in a curvilinear path, as shown in **FIG. 37** by proceeding with the suture around the bile duct **236** and the opening in the bowel. The first insertion point of the suture may be either in the bowel or the bile duct.

[0114] The appendix **240** is being removed from the cecum **242** of the large intestine in **FIG. 38**. Prior to cutting of the appendix **240**, the suture **40** must be placed so that it will be ready to tie off the appendiceal stump **244**. The suture **40** may be placed using a curved insertion device (not shown), or with curved needles **46, 48**. The barbed suture **40** is placed around the base of the appendix **240** by inserting the first end of the first portion of the suture at an insertion point **62** (**FIG. 39**) and pushing the first portion **54** in one direction through the muscularis and serosal layers of the cecum **242** around the base for at least one half of the circumference. Then the second portion **56** is likewise placed by inserting at the insertion point **62** and pushing the second portion **56** in the other direction through the muscularis and serosal layers of the cecum **242** around the base for at least until the second portion **56** crosses the first portion **54**. The appendix **240** is then removed, and the stump **244** is inverted while the suture **40** is pulled taut, similar to a "purse-string" as well as the alpha stitch shown in **FIGS. 19-22**.

[0115] Although **FIG. 38** shows both needles **50, 52** and respective suture end portions **54, 56** extending from the cecum **242**, having both end portions **54, 56** extend from the cecum **242** is optional. With the use of an insertion device of the nature of that shown in **FIG. 33**, for example (device

220), one end may be left embedded in the cecum **242** and the other end may be pulled to invert the appendiceal stump **244** with the purse-string or alpha stitch.

[0116] **FIGS. 40-42** show three stages of the procedure for a Zenker's Diverticulectomy. A Zenker's Diverticulum **260** is a sac that protrudes from the esophagus **262** below the pharynx **264**. The Diverticulum **260** is the herniation of the mucosal sac between the fibers of the pharyngeal constrictor muscle and the cricopharyngeal muscle **266**. The Diverticulum forms an orifice **268** to the lumen **270** of the esophagus **262**, and is shown in its initial untreated position in **FIG. 40**.

[0117] In **FIG. 41** the Diverticulum **260** is inverted and pulled into the esophagus **262** through the orifice **268** using an endoscopic grasping tool **272**. An endoscopic insertion device **274**, similar to the laparoscopic insertion device **220** of **FIGS. 32-34**, is used as shown in **FIG. 42** to insert the barbed suture **40** into the cricopharyngeal muscle **266** above the orifice **268**, exiting at the orifice, and then again penetrating the muscle **266**. The muscle **266** on both sides of the orifice **268** is approximated to close the orifice. The Diverticulum **260** is then endoscopically cut and removed (not shown). Alternatively, the stitch used to close the orifice **268** may be a purse-string type or alpha type, as shown in **FIGS. 38 and 39**. Multiple sutures may be used to close the orifice. Further, the procedure of suturing closed the orifice may be performed in a similar manner without inverting the Diverticulum **260** into the esophagus **262**. In this alternative the Diverticulum remains outside the esophagus **262** and is not excised.

[0118] The viscus structure **300** shown in **FIGS. 43-44** has an ulcerative lesion **302** on its inside wall **304**. An endoscopic camera **306** ("scope") allows the procedure to be performed, and an endoscopic insertion device (not shown) in a separate tube within the scope inserts the sutures **40** as previously described. The scope **306** may approach the lesion **302** through the anus or the oropharynx. The tissue on each side of the lesion **302** is approximated and the endoscopic devices are removed as shown in **FIG. 44**.

[0119] **FIGS. 45 and 46** respectively show a closure of a cystostomy incision in a urinary bladder **320**. The closure is shown as having a curvilinear path, and may be inserted in such a curvilinear path similarly to the sinusoidal method (**FIG. 45**) or coil method (**FIG. 46**) previously discussed and shown by **FIGS. 7-10** and **FIGS. 12-15**, respectively, although other methods discussed herein may also be used. The suture **40** passes through the muscularis layer of the bladder in a bidirectional fashion.

[0120] A replacement heart valve **340** is shown in **FIG. 47**. The annular cuff **342** of the heart valve **340** forms the periphery of the valve. The cuff **342** is joined to fibrous heart tissue **344** that forms a ring in the location where the valve **340** is placed. Two sutures **40a, 40b** are shown, respectively having first portions **54a** and **54b** that pass through the cuff **342** and tissue **344** in one direction and second portions **56a** and **56b** that proceed in the other direction. Threading of the sutures **40a, 40b** is performed similarly to the sinusoidal and coil methods previously discussed, and may start from either the cuff **342** or the tissue **344**.

[0121] Various configurations may be used to install the valve **340** in accordance with the knowledge of one of ordinary skill in the art, such as only one suture for the full

periphery of the valve, or multiple sutures that each include a portion of the valve's periphery, and providing redundancy of sutures as appropriate. The replacement heart valve may be a bioprosthetic valve or an artificial prosthetic mechanical valve. In addition, this method may be used on any foreign element that has a periphery and requires attachment to tissue, for example, a patch for closing a septal defect in the heart.

[0122] The method according to the present invention may also be used to secure devices to tissue, both inside and outside of a body. A central line device **360**, as used for intravenous access, is shown in **FIG. 48**, and is attached to a person's leg **362**. Examples of other devices that are required to be secured include catheters and monitors; tumor monitors in particular are an example of an internal device that may benefit from the method of the present invention. Eyelets **364a**, **364b** are provided on the device **360** and the suture **40** passes through each eyelet **364a**, **364b** before penetrating and passing through tissue of the leg **362** in a manner similar to that previously described, and being pulled snug to secure the device **360**.

[0123] To facilitate removal of the barbed suture **40**, the suture **40** may be cut at a point within the central portion **366**, separating the portions of the suture **40** with opposing barbs. Then the separate sections **54**, **56** of the suture **40** may be removed by pulling on an exposed portion in the direction that the barbs allow movement of the suture **40** through the tissue. This method of removal is not limited to the use shown in **FIG. 48**, but may apply to any use of the barbed suture.

[0124] The barbed sutures of the present invention may also be used in a variety of cosmetic surgery applications. Such applications include but are not limited to facelifts, browlifts, breast lifts, and thigh lifts. In each of the procedures, once the sutures are in place and as tension is maintained on the free ends of the suture (not shown in the figures referenced below), the engaged tissues are manually grouped and advanced toward the insertion point to achieve the desired lifting effect. The tissue into which the sutures are inserted are soft tissue, meaning any tissue that is not an organ or a vessel. Multiple sutures may be used for further augmentation or maintenance of lift.

[0125] A facelift and two methods of browlifts are shown in **FIG. 49**. One end **380** of a barbed suture **382** is inserted using a needle (not shown) at the temporal hairline at point **384** and advanced through the subepidermal tissue underneath the scalp, exiting distally. Subepidermal tissue comprises the papillary dermis, reticular dermis, subcutaneous tissue, or any combination thereof. The other end **386** is inserted at the same location and extended towards the nasolabial fold **388**, engaging the subepidermal tissue, the superficial muscular aponeurotic system, or both, and exiting distally. As tension is maintained on the free ends (not shown) of the suture **382**, the engaged tissues on the lower end **386** are manually grouped and advanced toward the insertion point **384** to achieve the desired lifting effect. The procedure is repeated on the opposite side of the face. Similar procedures may be performed to provide the lifts made in other locations with barbed sutures **390**, **400**.

[0126] In addition, the barbed sutures may be applied with the use of an insertion device as previously discussed. For

example, the barbed sutures **382**, **390** shown in **FIG. 49** may be put in place using an insertion device from either end of the respective suture.

[0127] One method of performing a browlift is shown with one end **408** of a barbed suture **410** being inserted at point **412** at the hairline (for nonreceding hairlines, as depicted) or at the midpoint between the hairline and the eyebrow (for receding hairlines, not shown). This end **408** is advanced through the subepidermal tissue towards and on through the scalp. The other end **414** is inserted at the same point and advanced through the subepidermal tissue in the opposite direction, exiting at the inferior aspect **416** of the brow. The procedure is repeated on the opposite side of the forehead, but for convenience herein a different method is shown in the same figure. Once again, the suture **410** may be put in place with the use of an insertion device from either end.

[0128] A second method of performing a browlift is shown in **FIG. 49** with one end **420** of a barbed suture **422** being inserted at point **424** at the hairline (for nonreceding hairlines, as depicted) or between the hairline and the eyebrow (for receding hairlines, not shown). This end **420** is advanced through the subepidermal tissue, exiting at the inferior aspect **426** of the brow. The other end **428** is inserted at the same point and is also advanced through the subepidermal tissue, but at a slight angle to the path taken by the first end **420** and also exiting at the inferior aspect **426** of the brow. This results in the approximate inverted vee-shaped configuration shown. The procedure may be repeated across the forehead.

[0129] Barbed sutures of the present invention may similarly be used as a tissue-sculpting device to perform a thigh or breast lifting procedure. These procedures are similar to those shown for the facelift and browlift of **FIG. 49**, and accordingly no additional drawings are required but respective descriptions are as follows.

[0130] To perform a thigh lift, multiple sutures are inserted by needle at the inguinal crease, spaced approximately 0.5-1.5 cm apart, beginning at the lateral aspect of the pubic triangle and extending medially approximately 180 degrees to the vicinity of the gluteal fold. The suture is advanced approximately 8 cm cranially through the subepidermal tissue. The opposite end of the suture is inserted in the same location and similarly advanced approximately 8 cm caudally. After exiting through the skin distally at each end, tension is maintained on the free ends of the suture, and the engaged tissues are manually grouped and advanced toward the insertion point to achieve the desired lifting effect. The process is repeated with multiple sutures around the semi-circumference of the thigh, and then repeated on the opposite thigh.

[0131] To perform a breast lift using a barbed suture of the present invention, one end of the barbed suture is inserted by needle into the skin at the upper aspect of the breast curvature. The needle is advanced such that the medial barbs engage the subcutaneous and dermal tissues, while the distal barbs engage the pectoralis muscle (and where possible, the periosteum of the clavicle), and then exit distally through the skin. The other end of the suture is inserted at the same point by needle, and advanced caudally through the fibrous and fatty tissues of the breast exiting at various points along the lower curvature of the breast. Additional sutures are similarly inserted at a variety of appropriately spaced locations

along the breast. As tension is maintained on the free suture ends, the breast is lifted along the axis of the suture, with the barbs locking the lift into place. Lifting is continued until the desired effect is achieved. Results from such a procedure may benefit from the use of a barbed suture with longer barbs than may be necessary in other procedures, in order to grasp fatty breast tissue effectively.

[0132] In FIG. 50, an insertion device 500 is shown in a procedure to close an axial wound in a blood vessel, such as an artery or vein. The wound 112 is similar to that shown in FIG. 22, but the method is different in that the method of FIG. 22 uses needles and does not penetrate the artery 114, rather constricting the tissue above and around the arterial opening. The insertion device 500 of FIG. 50 comprises a tubular body in which the barbed suture 50 is disposed. The wound 112 may be a puncture in an artery 114 as occurs as the result of the introduction and removal of catheters, as discussed in the text accompanying FIG. 22. The sharp pointed end 50 of the suture 40 is pushed with the leading end of the insertion device 500 through the skin 58 and tissue 70 on one side of the artery 114, through the artery wall on one side of the wound 112, into the interior 504 of the blood vessel 114, through the artery wall on the other side of the wound 112, and into the tissue 64 on the other side of the wound 112. The trailing end of the insertion device 500 is then pulled on to remove the insertion device 500, leaving the suture 40 in place.

[0133] Two embodiments of a suture left in place by an insertion device are shown in FIGS. 51 and 52. In FIG. 51, the portion 506 of the suture 40 in the interior 504 of the artery 114 has barbs. The embodiment of FIG. 52 omits barbs in the interior 504 of the artery 114, and the barbs are omitted for a portion 508 that extends into the artery 114 wall. The portion 508 without barbs could extend less or more than shown, and into the tissue 70, 64, so long as there are no barbs inside the artery 114. To reduce the chance of clotting of blood on or around the suture, an antithrombotic agent may be applied on the suture. Although FIGS. 50-51 show the suture 40 with the pointed end 50 embedded in tissue 70, 64, the suture 40 may also be put into place with the pointed end 50, or both ends, extending out of the skin 58, where the end or ends may be cut.

[0134] The invention is further illustrated by the following non-limiting examples.

EXAMPLE 1

[0135] A straight incision wound, about 1.5 cm deep, was created in each of four samples of cadaveric porcine skin tissue. The tissue samples measured 4 cm by 10 cm. Each incision was centered on the skin sample so that the wound was 4 cm long from end to end.

[0136] Each wound was closed according to a different suture method using identical barbed sutures made from monofilament PDS (polydioxanone) size 0. One wound was closed according to the method shown in U.S. Pat. Nos. 5,342,376 and 6,241,747, without using the inserting device ("the Ruff method"). Seven sutures were placed along the length of the wound and running generally perpendicularly to the faces of the wound. When placed, the sutures dipped below the incision line thus engaging subcutaneous tissue below the incision and the ends of the sutures engaged some dermis. A second wound was closed using seven needle-

tipped sutures placed along the length of the wound in the dermis and running generally perpendicularly to the faces of the wound similar to the method shown in U.S. Pat. No. 5,931,855 ("the Buncke method"). In both methods, the length of each suture buried under the skin was approximately 6 cm. A third wound was closed using the "zigzag" stitch pattern in the dermis as described above and shown in FIGS. 3-6. The number of passes resulted in four entry/exit points on each side of the wound. A fourth wound was closed using the corkscrew-shaped stitch pattern described above and shown in FIGS. 12-15. The number of passes resulted in seven complete loops with the tops of the loops engaged in the dermis. The tissues were held together only by the sutures.

[0137] Biomechanical strength testing was carried out as follows. Each sample was positioned so that the surface of the tissue sample was substantially vertical and the incision was generally horizontal. The bottom edge of the sample was immovably secured. The upper edge of the sample was attached to a Berkley digital fish scale (0-50 lb.) The scale was then raised vertically generating tension across the wound. The scale was raised until the tissues totally separated. The peak force required to separate the incision was recorded as the breaking strength.

TABLE 1

Suture Method	Breaking Strength (lbs.)
Ruff Method	4.5
Buncke Method	8.5
Zigzag Method	18.3
Corkscrew Method	16.5

EXAMPLE 2

[0138] Seven incisions were made at various locations on each of three dogs. The length of the incisions ranged from 2 inch to 4 inches and the depth of the incisions from the dermis to the muscular level. The incisions were closed with barbed sutures made from monofilament PDS (polydioxanone) size 0 and conventional sutures according to the following scheme with the locations randomized:

TABLE 2

Tissue Level	Barbed Suture Method	Conventional Suture Method
Dermis	Alpha, Zigzag	Simple interrupted loop stitches [2-0 nylon, 2-0 silk]
Subcuticular	Corkscrew	Simple continuous loop stitches [3-0 PDS]
Subcutaneous	Corkscrew	Simple continuous loop stitches [3-0 PDS]
Muscular	Corkscrew	Simple continuous loop stitches [3-0 PDS]

[0139] More than one alpha-shaped stitch was used for longer incisions.

[0140] The dogs were housed for two weeks. Daily clinical and necropsy observations were performed on all surgical sites. With the exception that three of six sites closed by nylon sutures had some sutures chewed out by the dog, all incisions healed normally and no dehiscence occurred. The other three sites closed with nylon sutures had a "railroad-

tile" appearance, one site in particular being very pronounced. None of the topical skin sites closed with barbed sutures had such an appearance. This example shows the efficacy of barbed sutures in an in vivo model.

[0141] The methods of the present invention have a number of advantages, including improving the biomechanical performance of barbed sutures. The curvilinear placement paths of the suture, as contrasted with linear insertion, provide substantially increased strength for holding the edges of a wound together. Moreover, the insertion of a single suture with curvilinear techniques replaces the insertion of a plurality of sutures. The new methods provide an efficient means for a surgeon to close a wound, reducing the time necessary to place the suture and the trauma to the patient. Surgeons can quickly and easily utilize the suturing methods during any type of surgery to quickly join the edges of a wound in tissue without threading and tying numerous individual stitches. The new suture methods are performed in a manner similar to conventional suturing thus realizing the advantages thereof. The methods minimize damage to tissue when inserted and minimize scarring or tissue necrosis across the wound. The sutures can be placed in the tissue in a manner to control and adjust the tension on the suture or the compression of the tissue.

[0142] Although the present invention has been shown and described in considerable detail with respect to only a few exemplary embodiments thereof, it should be understood by those skilled in the art that we do not intend to limit the invention to the embodiments since various modifications, omissions and additions may be made to the disclosed embodiments without materially departing from the novel teachings and advantages of the invention, particularly in light of the foregoing teachings. For example, the methods of the present invention can be used alone or with other closure methods, such as topical skin adhesives to aid in holding the position of the tissue. Accordingly, we intend to cover all such modifications, omission, additions and equivalents as may be included within the spirit and scope of the invention as defined by the following claims.

What is claimed is:

1. A method for joining and holding portions of a stomach to each other in the performance of a Nissen fundoplication procedure, the procedure requiring grasping the fundus of the stomach at a proximal location and pulling the fundus around the esophagus, wrapping the fundus around the esophagus one time and attaching the proximal stomach to an apposing portion of the stomach, the attachment made using a barbed suture including an elongated body, first and second sharp pointed distal ends for penetrating tissue, and a plurality of barbs extending from the periphery of the body, the barbs on a first portion of the body between the first end of the suture and a first axial location on the body for permitting movement of the suture through the tissue in a direction of movement of the first end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the first end, and the barbs on a second portion of the body between the second end of the suture and a second axial location on the body which is less than the distance from the second end to the first axial location permitting movement of the suture through the tissue in a direction of movement of the second end and preventing movement of the suture relative to the

tissue in a direction opposite the direction of movement of the second end, the method comprising the steps of:

- (a) inserting the first pointed end of the suture into tissue of the proximal stomach;
- (b) pushing the first end of the suture through the stomach tissue until the first end of the suture extends out of the tissue at an exit point on the exterior of the stomach;
- (c) gripping and pulling the first end of the suture to draw the first portion of the suture through the tissue until the second axial location is proximate to the point of insertion of the first end of the suture and leaving a length of the first portion of the suture in the tissue between the point of insertion and exit point of the first end;
- (d) gripping the proximal stomach and wrapping the fundus around the esophagus until the proximal stomach contacts an apposing portion of stomach;
- (e) inserting the second pointed end of the suture into tissue of the apposing stomach;
- (f) pushing the second end of the suture through the stomach tissue until the second end of the suture extends out of the tissue at an exit point on the exterior of the stomach; and
- (g) gripping and pulling the second end of the suture to draw the second portion of the suture through the tissue until the second axial location is proximate to the point of insertion of the second end of the suture and leaving a length of the second portion of the suture in the tissue between the point of insertion and exit point of the second end.

2. A method for joining and holding portions of a stomach to each other in the performance of a Nissen fundoplication procedure, the procedure requiring grasping the fundus of the stomach at a proximal location and pulling the fundus around the esophagus, wrapping the fundus around the esophagus one time and attaching the proximal stomach to an apposing portion of the stomach, the attachment made using a barbed suture including an elongated body, first and second sharp pointed distal ends for penetrating tissue, and a plurality of barbs extending from the periphery of the body, the barbs on a first portion of the body between the first end of the suture and a first axial location on the body for permitting movement of the suture through the tissue in a direction of movement of the first end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the first end, and the barbs on a second portion of the body between the second end of the suture and a second axial location on the body which is less than the distance from the second end to the first axial location permitting movement of the suture through the tissue in a direction of movement of the second end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the second end, and using an insertion device including a tubular element in which the suture is initially disposed, the insertion device having leading and trailing ends with openings therein with the first end of the suture proximate to the leading end, the method comprising the steps of:

- (a) gripping the proximal stomach and wrapping the fundus around the esophagus until the proximal stom-

ach contacts an apposing portion of stomach and forms a junction of the proximal and the apposing stomach tissues;

- (b) inserting the first pointed end of the suture and leading end of the insertion device into stomach tissue at a point laterally spaced from the junction and on a first side of the junction;
- (c) pushing the first end of the suture and leading end of the insertion device through the first side of stomach tissue and penetrating the stomach tissue on a second side of the junction until the portion of the suture between the first and second axial locations is proximate to the junction; and
- (d) gripping and pulling the insertion device at the trailing end to remove the insertion device, leaving the suture in place.

3. A method for joining and holding portions of a stomach to each other in the performance of a Nissen fundoplication procedure, the procedure requiring grasping the fundus of the stomach at a proximal location and pulling the fundus around the esophagus, wrapping the fundus around the esophagus one time and attaching the proximal stomach to an apposing portion of the stomach, the attachment made using a barbed suture including an elongated body, first and second sharp pointed distal ends for penetrating tissue, and a plurality of barbs extending from the periphery of the body, the barbs on a first portion of the body between the first end of the suture and a first axial location on the body for permitting movement of the suture through the tissue in a direction of movement of the first end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the first end, and the barbs on a second portion of the body between the second end of the suture and a second axial location on the body which is less than the distance from the second end to the first axial location permitting movement of the suture through the tissue in a direction of movement of the second end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the second end, the method comprising the steps of:

- (a) gripping the proximal stomach and wrapping the fundus around the esophagus until the proximal stomach contacts an apposing portion of stomach and forms a junction of the proximal and the apposing stomach tissues;
- (b) inserting the first pointed end of the suture into the tissue at a first side of the junction;
- (c) pushing the first end of the suture through the tissue until the first end of the suture extends out of the tissue at an exit point in the face of the junction below the surface of the tissue at the first side of the junction;
- (d) gripping the first end of the suture and pulling the first end out of the tissue for drawing the first portion of the suture through the tissue until the second axial location is at the point of insertion of the first end of the suture and leaving a length of the first portion of the suture in the tissue between the point of insertion in the first side of the junction and the exit point in the face of the junction at the first side of the junction;
- (e) inserting the first end of the suture into the face of the tissue below the surface of the tissue at a second side of the junction;

- (f) pushing the first end of the suture through the tissue until the first end of the suture extends out of the tissue at an exit point on the second side of the junction longitudinally spaced in a first direction from the insertion point in the first side of the junction;

- (g) gripping the first end of the suture and pulling the first end out of the tissue for drawing the first portion of the suture through the tissue while bringing the two sides of the junction together to a closed position along the first portion of the suture in the tissue and leaving a length of the first portion of the suture in the tissue between the point of insertion in the first side of the junction and the exit point in the second side of the junction;

- (h) inserting the second pointed end of the suture into the tissue at one side of the junction;

- (i) pushing the second end of the suture through the tissue until the second end of the suture extends out of the tissue at an exit point in the face of the tissue below the surface of the tissue at the one side of the junction;

- (j) gripping the second end of the suture and pulling the second end out of the tissue for drawing the second portion of the suture through the tissue until the second axial location is at the point of insertion of the second end of the suture and leaving a length of the second portion of the suture in the tissue between the point of insertion in the one side of the junction and the exit point in the face of the junction at the one side of the junction;

- (k) inserting the second end of the suture into the face of the tissue below the surface of the tissue at the other side of the junction;

- (l) pushing the second end of the suture through the tissue until the second end of the suture extends out of the tissue at an exit point on the other side of the junction longitudinally spaced in a second direction from the point of insertion of the second end of the suture at the one side of the junction; and

- (m) gripping the second end of the suture and pulling the second end out of the tissue for drawing the second portion of the suture through the tissue while bringing the sides of the junction together to the closed position along the second portion of the suture in the tissue and leaving a length of the second portion of the suture in the tissue between the point of insertion in the one side of the junction and the exit point in the other side of the junction.

4. A method for joining and holding portions of a stomach to each other as recited in claim 3, wherein the initial point of insertion of the first pointed end of the suture is laterally spaced from the face of the junction at the first side of the junction.

5. A method for joining and holding portions of a stomach to each other as recited in claim 3, wherein the initial point of insertion of the first pointed end of the suture is into the face of the junction below the surface of the tissue at the first side of the junction.

6. A method for joining and holding portions of a stomach to each other as recited in claim 3, wherein the steps of pushing the ends of the suture through the tissue comprise pushing the suture along a curvilinear path.

7. A method for joining and holding portions of a stomach to each other as recited in claim 3, wherein the steps of pushing the ends of the suture comprise pushing the suture along a straight path.

8. A method for joining and holding portions of a stomach to each other in the performance of a Nissen fundoplication procedure, the procedure requiring grasping the fundus of the stomach at a proximal location and pulling the fundus around the esophagus, wrapping the fundus around the esophagus one time and attaching the proximal stomach to an apposing portion of the stomach, the attachment made using a barbed suture including an elongated body, first and second sharp pointed distal ends for penetrating tissue, and a plurality of barbs extending from the periphery of the body, the barbs on a first portion of the body between the first end of the suture and a first axial location on the body for permitting movement of the suture through the tissue in a direction of movement of the first end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the first end, and the barbs on a second portion of the body between the second end of the suture and a second axial location on the body which is less than the distance from the second end to the first axial location permitting movement of the suture through the tissue in a direction of movement of the second end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the second end, the method comprising the steps of:

- (a) gripping the proximal stomach and wrapping the fundus around the esophagus until the proximal stomach contacts an apposing portion of stomach and forms a junction of the proximal and the apposing stomach tissues;
- (b) inserting the first pointed end of the suture into the stomach tissue below the surface of the stomach tissue at a first face of the junction;
- (c) pushing the first end of the suture through the stomach tissue along a curvilinear path until the first end of the suture extends from the stomach tissue at an exit point in the first face of the junction longitudinally spaced in a first direction from the insertion point in the first face of the junction;
- (d) gripping the first pointed end of the suture and pulling the first end out of the stomach tissue for drawing the first portion of the suture through the stomach tissue until the second axial location is at the point of insertion of the first end of the suture in the first face of the junction and leaving a length of the first portion of the suture in the stomach tissue of the junction;
- (e) inserting the first pointed end of the suture at a point below the surface of the stomach tissue in a second face of the junction;
- (f) pushing the first end of the suture through the stomach tissue along a curvilinear path until the first end of the suture extends from the stomach tissue at an exit point in the second face of the junction below the surface of the stomach tissue and longitudinally spaced in the first direction from the insertion point in the second face of the junction;
- (g) repeating steps (b) through (f) for advancing longitudinally along the junction in the first direction as necessary to one end of the junction;

(h) inserting the second pointed end of the suture into the stomach tissue of the second face of the junction below the surface of the stomach tissue and adjacent the initial point of insertion of the first end in the first face of the junction;

(i) pushing the second end of the suture through the stomach tissue along a curvilinear path until the second end of the suture extends from the stomach tissue at an exit point below the surface of the stomach tissue in the second face of the junction and longitudinally spaced in a second direction from the point of insertion in the second face of the junction;

(j) gripping the second pointed end of the suture and pulling the second end out of the stomach tissue for drawing the second portion of the suture through the stomach tissue until the second axial location is at the point of insertion of the second pointed end in the second face of the junction and leaving a length of the second portion of the suture in the stomach tissue of the junction;

(k) inserting the second pointed end of the suture at a point in the first face of the junction below the surface of the stomach tissue;

(l) pushing the second end of the suture through the stomach tissue along a curvilinear path until the second end of the suture extends from the stomach tissue at an exit point in the first face of the junction below the surface of the stomach tissue and longitudinally spaced in the second direction from the point of insertion of the second end of the suture in the first face of the junction; and

(m) repeating steps (h) through (l) for advancing longitudinally along the junction in the second direction to the other end of the junction.

9. A method for joining and holding portions of a stomach to each other as recited in claim 8, wherein the initial point of insertion of the first pointed end of the suture is adjacent an end of the junction and the first direction and second direction are the same direction.

10. A method for joining and holding portions of a stomach to each other as recited in claim 8, wherein initial point of insertion of the first pointed end of the suture is longitudinally spaced from and between the ends of the junction and the first direction and second direction are opposite directions.

11. A method for laparoscopically inserting a suture in a surgical procedure, using a barbed suture including an elongated body, first and second sharp pointed distal ends for penetrating tissue, and a plurality of barbs extending from the periphery of the body, the barbs on a first portion of the body between the first end of the suture and a first axial location on the body for permitting movement of the suture through the tissue in a direction of movement of the first end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the first end, and the barbs on a second portion of the body between the second end of the suture and a second axial location on the body which is less than the distance from the second end to the first axial location permitting movement of the suture through the tissue in a direction of movement of the second end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of

the second end, and using a laparoscopic insertion device including a tubular element in which the suture is initially disposed, the insertion device having leading and trailing ends with openings therein with the first end of the suture proximate to the leading end, the method comprising the steps of:

- (a) inserting the first pointed end of the suture and the leading end of the laparoscopic insertion device through the skin, and then through the fat, fascia, muscle, and peritoneum into the abdominal cavity;
- (b) inserting the first end of the suture and leading end of the insertion device into tissue in the abdominal cavity at an entry point and pushing the first end of the suture and leading end of the insertion device into the tissue in the abdominal cavity; and
- (c) gripping and pulling the insertion device at the trailing end to remove the insertion device, leaving the suture in place.

12. A method for laparoscopically inserting a suture in a surgical procedure as recited in claim 11, wherein the procedure comprises stabilizing a bowel structure in position in preparation for additional procedures such as a laparoscopic anastomosis and the tissue in the abdominal cavity into which the suture is inserted is bowel tissue, and further comprising the steps of:

- (a) gripping and positioning the bowel structure in a location for stabilization; and
- (b) leaving the inserted suture in place in the bowel tissue and the abdominal wall.

13. A method for laparoscopically inserting a suture in a surgical procedure as recited in claim 11, wherein the procedure comprises a closure of a wound resulting from a cystostomy, the tissue into which the suture is inserted is urinary bladder muscularis, the entry point in the muscularis tissue is spaced from and on one side of the wound, and the first end of the suture and leading end of the insertion device are pushed through the tissue until the first end of the suture and the leading end of the insertion device extend out of the tissue at the wound, and further comprising the steps of:

- (a) inserting the first pointed end of the suture and the leading end of the insertion device through an opposing side of the wound;
- (b) pushing the first end of the suture and leading end of the insertion device through the tissue until the second axial location is proximate to a central to the point of the wound; and
- (c) advancing the tissue on the two sides of the lesion together as necessary to close the wound.

14. A method for performing an anastomosis of the liver bile duct to a bowel structure, the bile duct having one end connected to the liver and a free end after having been severed, and the bowel structure having an opening in its wall made to receive the annular free end of the bile duct, using a barbed suture including an elongated body, first and second sharp pointed distal ends for penetrating tissue, and a plurality of barbs extending from the periphery of the body, the barbs on a first portion of the body between the first end of the suture and a first axial location on the body for permitting movement of the suture through the tissue in a direction of movement of the first end and preventing

movement of the suture relative to the tissue in a direction opposite the direction of movement of the first end, and the barbs on a second portion of the body between the second end of the suture and a second axial location on the body which is less than the distance from the second end to the first axial location permitting movement of the suture through the tissue in a direction of movement of the second end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the second end, and using an insertion device including a tubular element in which the suture is initially disposed, the insertion device having leading and trailing ends with openings therein with the first end of the suture proximate to the leading end, the method comprising the steps of:

- (a) placing the free end of the bile duct in contact with the opening in the bowel structure, forming a junction at the annular contact area between the bile duct tissue and the bowel structure tissue;
- (b) inserting the first pointed end of the suture and the leading end of the insertion device into the tissue on one side of the junction;
- (c) pushing the first end of the suture and leading end of the insertion device through the tissue on one side of the junction, through the junction, and penetrating tissue on the other side of the junction;
- (d) gripping and pulling the insertion device at the trailing end to remove the insertion device, leaving the suture in place in both the bile duct tissue and the bowel structure tissue;
- (e) repeating steps (b) through (d) with additional sutures around the junction as necessary to provide an anastomotic seal at the junction.

15. A method for performing an anastomosis of the liver bile duct to a bowel structure, the bile duct having one end connected to the liver and a free end after having been severed, and the bowel structure having an opening in its wall made to receive the annular free end of the bile duct, the bile duct comprising one of a first tissue and a second tissue, and the bowel tissue comprising the other of the first tissue and second tissue, using a barbed suture including an elongated body, first and second sharp pointed distal ends for penetrating tissue, and a plurality of barbs extending from the periphery of the body, the barbs on a first portion of the body between the first end of the suture and a first axial location on the body for permitting movement of the suture through the tissue in a direction of movement of the first end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the first end, and the barbs on a second portion of the body between the second end of the suture and a second axial location on the body which is less than the distance from the second end to the first axial location permitting movement of the suture through the tissue in a direction of movement of the second end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the second end, the method comprising the steps of:

- (a) placing the free end of the bile duct in contact with the opening in the bowel structure, forming a junction at the annular contact area between the bile duct tissue and the bowel structure tissue;
- (b) inserting the first pointed end of the suture into the first tissue at a point spaced from the junction;

- (c) pushing the first end of the suture through the first tissue until the first end of the suture extends out of the first tissue at an exit point and penetrating the second tissue at a face of the junction until the first end of the suture extends out of the second tissue at an exit point spaced from the junction and spaced in a first direction along the circumference of the junction from the point of insertion of the first end of the suture in the first tissue;
 - (d) gripping the first end of the suture and pulling the first end out of the second tissue for drawing the first portion of the suture through the first tissue and the second tissue while bringing the first tissue and the second tissue together to a closed position along the first portion of the suture until the second axial location is at the point of insertion of the first end of the suture at the one side of the first tissue and leaving a length of the first portion of the suture in the first tissue and the second tissue between the point of insertion and the exit point;
 - (e) inserting the first end of the suture into the second tissue at the exit point of the first end;
 - (f) pushing the first end of the suture through the second tissue until the first end of the suture extends out of the second tissue at an exit point in the face of the junction and penetrating the first tissue until the first end of the suture extends out of the first tissue at an exit point spaced from the junction and spaced along the circumference of the junction in the first direction from the immediately preceding point of insertion of the first end of the suture in the first tissue;
 - (g) gripping the first end of the suture and pulling the first end out of the first tissue for drawing the first portion of the suture through the second tissue while bringing the first tissue and the second tissue together to a closed position along the first portion of the suture and leaving a length of the first portion of the suture in the periphery between the point of insertion and the exit point;
 - (h) repeating steps (b) through (g) as necessary for advancing around the circumference of the junction along the second tissue in the first direction;
 - (i) inserting the second end of the suture into the first tissue at the insertion point of the first end;
 - (j) pushing the second end of the suture through the first tissue until the second end of the suture extends out of the first tissue at an exit point and penetrating the second tissue at a face of the junction until the second end of the suture extends out of the second tissue at an exit point spaced from the junction and spaced along the circumference of the junction in the second direction from the point of insertion of the second end of the suture in the first tissue; and
 - (k) gripping the second end of the suture and pulling the second end out of the second tissue for drawing the second portion of the suture through the tissue while bringing the first tissue and the second tissue together to the closed position along the second portion of the suture and leaving a length of the second portion of the suture in the first tissue and the second tissue between the point of insertion and the exit point;
 - (l) inserting the second pointed end of the suture into the second tissue at the exit point of the second end;
 - (m) pushing the second end of the suture through the second tissue until the second end of the suture extends out of the second tissue at an exit point in the face of the junction and penetrating the first tissue until the second end of the suture extends out of the first tissue at an exit point spaced from the junction and spaced along the circumference of the junction in a second direction from the point of insertion of the second end of the suture;
 - (n) gripping the second pointed end of the suture and pulling the second end out of the first tissue for drawing the second portion of the suture through the first tissue and second tissue while bringing the first tissue and the second tissue together to a closed position along the second portion of the suture until the second axial location is at the point of insertion of the first end of the suture at the one side of the junction and leaving a length of the second portion of the suture in the first tissue and the second tissue between the point of insertion and the exit point; and
 - (o) repeating steps (i) through (n) around the junction as necessary to provide an anastomotic seal at the junction.
- 16.** A method for tying off an appendiceal stump resulting from the performance of an appendectomy, the appendix extending from the cecum of the large intestine and having a base with a circumference at the juncture of the appendix and the cecum, using a barbed suture including an elongated body, first and second sharp pointed distal ends for penetrating tissue, and a plurality of barbs extending from the periphery of the body, the barbs on a first portion of the body between the first end of the suture and a first axial location on the body for permitting movement of the suture through the tissue in a direction of movement of the first end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the first end, and the barbs on a second portion of the body between the second end of the suture and a second axial location on the body which is less than the distance from the second end to the first axial location permitting movement of the suture through the tissue in a direction of movement of the second end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the second end, the method comprising the steps of:
- (a) inserting the first pointed end of the suture into tissue of the cecum proximate to the appendix base;
 - (b) pushing the first end of the suture around the circumference of the base in one direction for at least one half of the of the circumference of the base until extending through an exit point in the tissue;
 - (c) inserting the second pointed end of the suture into tissue of the cecum proximate to the entry point of the first end;
 - (d) pushing the second end of the suture along the circumference of the base in the other direction for at least one half of the of the circumference of the base until extending through an exit point in the tissue;
 - (e) excising the appendix, leaving the appendiceal stump; and

(f) gripping and pulling the ends of the suture, causing the suture to tighten around the appendiceal stump.

17. The method of claim 16, further comprising the step of inverting the appendiceal stump such that the stump is disposed within the cecum.

18. A method for joining and holding closed the muscle layers that define the orifice of a Zenker's Diverticulum, the Zenker's Diverticulum including a sac extending from a proximal location of the esophagus near the pharynx, the sac having walls including a muscle layer common to the proximal esophagus, using a barbed suture including an elongated body, first and second sharp pointed distal ends for penetrating tissue, and a plurality of barbs extending from the periphery of the body, the barbs on a first portion of the body between the first end of the suture and a first axial location on the body for permitting movement of the suture through the tissue in a direction of movement of the first end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the first end, and the barbs on a second portion of the body between the second end of the suture and a second axial location on the body which is less than the distance from the second end to the first axial location permitting movement of the suture through the tissue in a direction of movement of the second end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the second end, and using an endoscopic insertion device that passes through the mouth, throat, and pharynx, including a tubular element in which the suture is initially disposed, the insertion device having leading and trailing ends with openings therein with the first end of the suture proximate to the leading end, the method comprising the steps of:

- (a) inserting the first pointed end of the suture and the leading end of the endoscopic insertion device through an entry point in the esophageal muscle between the pharynx and the orifice, and spaced from the orifice on the side of the orifice towards the mouth;
- (b) pushing the first end of the suture and leading end of the insertion device through the muscle until the first end of the suture and the leading end of the insertion device extend out of the muscle at the orifice of the sac;
- (c) inserting the first pointed end of the suture and the leading end of the endoscopic insertion device through an opposing side of the orifice;
- (d) pushing the first end of the suture and leading end of the insertion device through the muscle until the second axial location is proximate to a central point of the orifice;
- (e) gripping and pulling the insertion device at the trailing end to remove the insertion device, leaving the suture in place;
- (f) optionally repeating steps (a) through (e) as desired with additional sutures; and
- (g) advancing the muscle on the two sides of the orifice together as necessary to close the orifice.

19. A method for joining and holding closed ulcerative lesions or post-procedural tissue defects on an interior surface of a viscus, using a barbed suture including an elongated body, first and second sharp pointed distal ends for penetrating tissue, and a plurality of barbs extending from

the periphery of the body, the barbs on a first portion of the body between the first end of the suture and a first axial location on the body for permitting movement of the suture through the tissue in a direction of movement of the first end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the first end, and the barbs on a second portion of the body between the second end of the suture and a second axial location on the body which is less than the distance from the second end to the first axial location permitting movement of the suture through the tissue in a direction of movement of the second end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the second end, and using an endoscopic insertion device, including a tubular element in which the suture is initially disposed, the insertion device having leading and trailing ends with openings therein with the first end of the suture proximate to the leading end, the method comprising the steps of:

- (a) inserting the first pointed end of the suture and the leading end of the endoscopic insertion device through an entry point in the tissue spaced from and on one side of the lesion;
- (b) pushing the first end of the suture and leading end of the insertion device through the tissue until the first end of the suture and the leading end of the insertion device extend out of the tissue at the lesion;
- (c) inserting the first pointed end of the suture and the leading end of the endoscopic insertion device through an opposing side of the lesion;
- (d) pushing the first end of the suture and leading end of the insertion device through the tissue until the second axial location is proximate to a central to the point of the lesion;
- (e) gripping and pulling the insertion device at the trailing end to remove the insertion device, leaving the suture in place; and
- (f) optionally repeating steps (a) through (e) as desired with additional sutures;
- (g) advancing the tissue on the two sides of the lesion together as necessary to close the lesion.

20. A method for joining and holding closed a wound in urinary bladder muscularis tissue to allow tissue healing and regrowth together of the sides of the wound, or reconfiguration in vivo, using a barbed suture including an elongated body, first and second sharp pointed distal ends for penetrating tissue, and a plurality of barbs extending from the periphery of the body, the barbs on a first portion of the body between the first end of the suture and a first axial location on the body for permitting movement of the suture through the tissue in a direction of movement of the first end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the first end, and the barbs on a second portion of the body between the second end of the suture and a second axial location on the body which is less than the distance from the second end to the first axial location permitting movement of the suture through the tissue in a direction of movement of the second end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the second end, the method comprising the steps of:

- (a) inserting the first pointed end of the suture into the tissue below the surface of the tissue at a first face of the wound at an initial point;
- (b) pushing the first end of the suture through the tissue along a curvilinear path until the first end of the suture extends from the tissue at an exit point in the first face of the wound and longitudinally spaced in a first direction from the insertion point in the first face of the wound;
- (c) gripping the first pointed end of the suture and pulling the first end out of the tissue for drawing the first portion of the suture through the tissue until the second axial location is at the point of insertion of the first end of the suture in the first face of the wound and leaving a length of the first portion of the suture in the tissue;
- (d) inserting the first pointed end of the suture at a point below the surface of the tissue in a second face of the wound;
- (e) pushing the first end of the suture through the tissue along a curvilinear path until the first end of the suture extends from the tissue at an exit point in the second face of the wound below the surface of the tissue and longitudinally spaced in the first direction from the insertion point in the second face of the wound;
- (f) repeating steps (a) through (e) for advancing longitudinally along the wound in the first direction as necessary to one end of the wound;
- (g) inserting the second pointed end of the suture into the tissue of the second face of the wound below the surface of the tissue and adjacent the initial point of insertion of the first end in the first face of the wound;
- (h) pushing the second end of the suture through the tissue along a curvilinear path until the second end of the suture extends from the tissue at an exit point below the surface of the tissue in the second face of the wound and longitudinally spaced in a second direction from the point of insertion in the second face of the wound;
- (i) gripping the second pointed end of the suture and pulling the second end out of the tissue for drawing the second portion of the suture through the tissue until the second axial location is at the point of insertion of the second pointed end in the second face of the wound and leaving a length of the second portion of the suture in the tissue;
- (j) inserting the second pointed end of the suture at a point in the first face of the wound below the surface of the tissue;
- (k) pushing the second end of the suture through the tissue along a curvilinear path until the second end of the suture extends from the tissue at an exit point in the first face of the wound below the surface of the tissue and longitudinally spaced in the second direction from the point of insertion of the second end of the suture in the first face of the wound; and
- (l) repeating steps (g) through (k) for advancing longitudinally along the wound in the second direction to the other end of the wound.

21. A method for joining and holding closed a wound in urinary bladder muscularis tissue as recited in claim 20,

wherein the initial point of insertion of the first pointed end of the suture is adjacent an end of the junction and the first direction and second direction are the same direction.

22. A method for joining and holding closed a wound in urinary bladder muscularis tissue as recited in claim 20, wherein the initial point of insertion of the first pointed end of the suture is longitudinally spaced from and between the ends of the junction and the first direction and second direction are opposite directions.

23. A method for joining and holding closed a wound in urinary bladder muscularis tissue to allow tissue healing and regrowth together of the sides of the wound, or reconfiguration in vivo, using a barbed suture including an elongated body, first and second sharp pointed distal ends for penetrating tissue, and a plurality of barbs extending from the periphery of the body, the barbs on a first portion of the body between the first end of the suture and a first axial location on the body for permitting movement of the suture through the tissue in a direction of movement of the first end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the first end, and the barbs on a second portion of the body between the second end of the suture and a second axial location on the body which is less than the distance from the second end to the first axial location permitting movement of the suture through the tissue in a direction of movement of the second end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the second end, the method comprising the steps of:

- (a) inserting the first pointed end of the suture into the muscularis tissue below the surface of the muscularis tissue at a first face of the wound at an initial point;
- (b) pushing the first end of the suture through the muscularis tissue along a curvilinear path until the first end of the suture extends from the muscularis tissue at an exit point in the first face of the wound longitudinally spaced in a first direction from the insertion point in the first face of the wound;
- (c) gripping the first pointed end of the suture and pulling the first end out of the muscularis tissue for drawing the first portion of the suture through the muscularis tissue until the second axial location is at the point of insertion of the first end of the suture in the first face of the wound and leaving a length of the first portion of the suture in the muscularis tissue of the wound;
- (d) inserting the first pointed end of the suture at a point below the surface of the muscularis tissue in a second face of the wound;
- (e) pushing the first end of the suture through the muscularis tissue along a curvilinear path until the first end of the suture extends from the muscularis tissue at an exit point in the second face of the wound below the surface of the muscularis tissue and longitudinally spaced in the first direction from the insertion point in the second face of the wound;
- (f) inserting the first end of the suture at a point in the first face of the wound below the surface of the muscularis tissue;
- (g) repeating steps (b) through (f) for advancing longitudinally along the wound in the first direction as necessary to one end of the wound;

- (h) inserting the second pointed end of the suture into the muscularis tissue of the second face of the wound below the surface of the muscularis tissue and adjacent the initial point of insertion of the first end in the first face of the wound;
 - (i) pushing the second end of the suture through the muscularis tissue along a curvilinear path until the second end of the suture extends from the muscularis tissue at an exit point below the surface of the muscularis tissue in the second face of the wound and longitudinally spaced in a second direction from the point of insertion in the second face of the wound;
 - (j) gripping the second pointed end of the suture and pulling the second end out of the muscularis tissue for drawing the second portion of the suture through the muscularis tissue until the second axial location is at the point of insertion of the second needle in the second face of the wound and leaving a length of the second portion of the suture in the muscularis tissue of the wound;
 - (k) inserting the second pointed end of the suture at a point in the first face of the wound below the surface of the muscularis tissue;
 - (l) pushing the second end of the suture through the muscularis tissue along a curvilinear path until the second end of the suture extends from the muscularis tissue at an exit point in the first face of the wound below the surface of the muscularis tissue and longitudinally spaced in the second direction from the point of insertion of the second end of the suture in the first face of the wound;
 - (m) inserting the second pointed end of the suture at a point in the first face of the wound below the surface of the muscularis tissue; and
 - (n) repeating steps (i) through (m) for advancing longitudinally along the wound in the second direction to the other end of the wound.
24. A method for joining and holding closed a wound in urinary bladder muscularis tissue as recited in claim 23, wherein the initial point is adjacent an end of the junction and the first direction and second direction are the same direction.
25. A method for joining and holding closed a wound in urinary bladder muscularis tissue as recited in claim 23, wherein the initial point is longitudinally spaced from and between the ends of the junction and the first direction and second direction are opposite directions.
26. A method for joining a foreign element and bodily tissue, the foreign element having a periphery, the bodily tissue having a fibrous tissue ring with a face of the fibrous tissue ring defining an opening and apposing a face of the periphery, with both the foreign element and the tissue comprising matter, and holding closed a junction between the element and the tissue to allow tissue healing and regrowth, or reconfiguration in vivo, using a barbed suture including an elongated body, first and second sharp pointed distal ends for penetrating tissue, and a plurality of barbs extending from the periphery of the body, the barbs on a first portion of the body between the first end of the suture and a first axial location on the body for permitting movement of the suture through the tissue in a direction of movement of the first end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the first end, and the barbs on a second portion of the body between the second end of the suture and a second axial location on the body which is less than the distance from the second end to the first axial location permitting movement of the suture through the tissue in a direction of movement of the second end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the second end, the method comprising the steps of:
- (a) inserting the first pointed end of the suture into matter on a first side of the junction at a point radially spaced from the junction;
 - (b) pushing the first end of the suture through the matter on the first side until the first end of the suture extends out of the first side matter at an exit point and penetrating the face of the matter on the second side of the junction until the first end of the suture extends out of the second side matter at an exit point radially spaced from the junction and spaced along the junction circumference in a first direction from the point of insertion of the first end of the suture in the first side matter;
 - (c) gripping the first end of the suture and pulling the first end out of the second side matter for drawing the first portion of the suture through the first and second side matter while bringing the first and second side matter together to a closed position along the first portion of the suture until the second axial location is at the point of insertion of the first end of the suture in the first side matter and leaving a length of the first portion of the suture in the first and second side matter between the point of insertion and the exit point;
 - (d) inserting the first end of the suture into the second side matter at the exit point of the first end;
 - (e) pushing the first end of the suture through the second side matter until the first end of the suture extends out of the second side matter at an exit point in the face of the second side matter and penetrating the first side matter until the first end of the suture extends out of the first side matter at an exit point radially spaced from the junction and spaced along the junction circumference in the first direction from the point of insertion of the first end of the suture in the first side matter;
 - (f) gripping the first end of the suture and pulling the first end out of the first side matter for drawing the first portion of the suture through the first and second side matter while bringing the first and second side matter together to a closed position along the first portion of the suture and leaving a length of the first portion of the suture in the first side matter between the point of insertion and the exit point;
 - (g) repeating steps (a) through (f), with each repetition advancing along the junction circumference in the first direction;
 - (h) inserting the second end of the suture into the first side matter at the insertion point of the first end;
 - (i) pushing the second end of the suture through the first side matter until the second end of the suture extends out of the first side matter at an exit point and pen-

etrating the face of the second side matter until the second end of the suture extends out of the second side matter at an exit point radially spaced from the junction and spaced along the junction circumference in the second direction from the point of insertion of the second end of the suture on the first side matter; and

- (j) gripping the second end of the suture and pulling the second end out of the second side matter for drawing the second portion of the suture through the second side matter while bringing the first side matter and the second side matter together to the closed position along the second portion of the suture and leaving a length of the second portion of the suture in the first and second side matter between the point of insertion and the exit point;
- (k) inserting the second pointed end of the suture into the second side matter at the exit point of the second end;
- (l) pushing the second end of the suture through the second side matter until the second end of the suture extends out of the second side matter at an exit point in the face of the second side matter and penetrating the first side matter until the second end of the suture extends out of the first side matter at an exit point radially spaced from the junction and spaced along the junction circumference in a second direction from the point of insertion of the second end of the suture;
- (m) gripping the second pointed end of the suture and pulling the second end out of the periphery for drawing the second portion of the suture through the first and second side matter while bringing the first and second side matter together to a closed position along the second portion of the suture until the second axial location is at the point of insertion of the first end of the suture in the second side matter and leaving a length of the second portion of the suture in the first and second side matter between the point of insertion and the exit point; and
- (n) repeating steps (h) through (m), with each repetition advancing along the junction circumference in the second direction.

27. A method for joining a foreign element and bodily tissue as recited in claim 26, wherein the foreign element is a bioprosthetic heart valve and the tissue is heart tissue.

28. A method for joining a foreign element and bodily tissue as recited in claim 26, wherein the foreign element is a mechanical prosthetic heart valve and the tissue is heart tissue.

29. A method for joining a foreign element and bodily tissue as recited in claim 26, wherein the foreign element is a bioprosthetic patch for cardiac septal defects and the tissue is heart tissue.

30. A method for joining a foreign element and bodily tissue as recited in claim 26, further comprising the step of continuing to advance the first portion and the second portion of the sutures at least until the entire periphery is joined to the tissue.

31. A method for joining a foreign element and bodily tissue as recited in claim 26, further comprising the step of continuing to advance the first portion and the second portion of the sutures until the first and second portion overlap for at least one quarter of the periphery.

32. A method for joining a foreign element and bodily tissue, the foreign element having a periphery, the bodily tissue having a fibrous tissue ring with a face of the fibrous tissue ring defining an opening and apposing a face of the periphery, with both the foreign element and the tissue comprising matter, and holding closed a junction between the element and the tissue to allow tissue healing and regrowth, or reconfiguration in vivo, using a barbed suture including an elongated body, first and second sharp pointed distal ends for penetrating tissue, and a plurality of barbs extending from the periphery of the body, the barbs on a first portion of the body between the first end of the suture and a first axial location on the body for permitting movement of the suture through the tissue in a direction of movement of the first end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the first end, and the barbs on a second portion of the body between the second end of the suture and a second axial location on the body which is less than the distance from the second end to the first axial location permitting movement of the suture through the tissue in a direction of movement of the second end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the second end, the method comprising the steps of:

- (a) inserting the first pointed end of the suture into the first side matter below the surface of the first side matter at a first face of the junction;
- (b) pushing the first end of the suture through the first side matter along a curvilinear path until the first end of the suture extends from the first side matter at an exit point in the first face of the junction below the surface of the first side matter and spaced along the junction circumference in a first direction from the insertion point in the first face of the junction;
- (c) gripping the first pointed end of the suture and pulling the first end out of the first side matter for drawing the first portion of the suture through the first side matter until the second axial location is at the point of insertion of the first end of the suture in the first face of the junction and leaving a length of the first portion of the suture in the first side matter;
- (d) inserting the first pointed end of the suture at a point below the surface of the second side matter in a second face of the junction;
- (e) pushing the first end of the suture through the second side matter along a curvilinear path until the first end of the suture extends from the second side matter at an exit point in the second face of the junction below the surface of the second side matter and spaced along the junction circumference in the first direction from the insertion point in the second face of the junction;
- (f) repeating steps (a) through (e) for advancing longitudinally along the junction circumference in the first direction;
- (g) inserting the second pointed end of the suture into the second side matter of the second face of the junction below the surface of the second side matter and adjacent the initial point of insertion of the first end in the first face of the wound;

- (h) pushing the second end of the suture through the second side matter along a curvilinear path until the second end of the suture extends from the second side matter at an exit point below the surface of the second side matter in the second face of the junction and spaced along the junction circumference in a second direction from the point of insertion in the second face of the junction;
- (i) gripping the second pointed end of the suture and pulling the second end out of the second side matter for drawing the second portion of the suture through the second side matter until the second axial location is at the point of insertion of the second pointed end in the second face of the junction and leaving a length of the second portion of the suture in the second side matter;
- (j) inserting the second pointed end of the suture at a point in the first face of the wound below the surface of the first side matter;
- (k) pushing the second end of the suture through the first side matter along a curvilinear path until the second end of the suture extends from the first side matter at an exit point in the first face of the junction below the surface of the first side matter and spaced along the junction circumference in the second direction from the point of insertion of the second end of the suture in the first face of the junction; and
- (l) repeating steps (g) through (k) for advancing longitudinally along the wound in the second direction to the other end of the wound.

33. A method for joining a foreign element and bodily tissue as recited in claim 32, wherein the foreign element is a bioprosthetic heart valve and the tissue is heart tissue.

34. A method for joining a foreign element and bodily tissue as recited in claim 32, wherein the foreign element is a mechanical prosthetic heart valve and the tissue is heart tissue.

35. A method for joining a foreign element and bodily tissue as recited in claim 32, wherein the foreign element is a bioprosthetic patch for cardiac septal defects and the tissue is heart tissue.

36. A method for joining a foreign element and bodily tissue as recited in claim 32, further comprising the step of continuing to advance the first portion and the second portion of the sutures at least until the entire periphery is joined to the tissue.

37. A method for joining a foreign element and bodily tissue as recited in claim 32, further comprising the step of continuing to advance the first portion and the second portion of the sutures until the first and second portion overlap for at least one quarter of the periphery.

38. A method of mounting a device to bodily tissue, the device including at least one eyelet for securing the device and through which a suture may pass, using a barbed suture including an elongated body, first and second sharp pointed distal ends for penetrating tissue, and a plurality of barbs extending from the periphery of the body, the barbs on a first portion of the body between the first end of the suture and a first axial location on the body for permitting movement of the suture through the tissue in a direction of movement of the first end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the first end, and the barbs on a second portion of

the body between the second end of the suture and a second axial location on the body which is less than the distance from the second end to the first axial location permitting movement of the suture through the tissue in a direction of movement of the second end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the second end, the method comprising the steps of:

- (a) placing the device in a desired position;
- (b) threading a suture through the at least one eyelet;
- (c) inserting the first pointed end of the suture into tissue;
- (d) pushing the first end of the suture through the tissue until the first end of the suture extends out of the tissue at an exit point;
- (e) gripping the first end of the suture and pulling the first end out of the tissue while drawing the first portion of the suture through the tissue, leaving a portion of the suture between the first and second axial locations out of the tissue and leaving a length of the first portion of the suture in the tissue between the point of insertion and exit point of the first end;
- (f) inserting the second pointed end of the suture into tissue;
- (g) pushing the second end of the suture through the tissue until the second end of the suture extends out of the tissue at an exit point, leaving a portion of the suture between the first and second axial locations out of the tissue; and
- (h) gripping the second end of the suture and pulling the second end out of the tissue while drawing the second portion of the suture through the tissue until the device is secured and leaving a length of the second portion of the suture in the tissue between the point of insertion and exit point of the second end;

wherein the first and second portions of the suture extend in the tissue in generally opposing directions and cause the suture to resist displacement of the device.

39. A method for mounting a device to bodily tissue as recited in claim 38, wherein the device is a catheter.

40. A method for mounting a device to bodily tissue as recited in claim 38, wherein the device is a tumor monitor.

41. A method for mounting a device to bodily tissue as recited in claim 38, wherein the device is an electrode of a cardiac pacemaker.

42. A method for mounting a device to bodily tissue as recited in claim 38, wherein the bodily tissue to which the device is mounted is an internal organ.

43. A method for mounting a device to bodily tissue as recited in claim 38, wherein the bodily tissue to which the device is mounted includes the skin.

44. A method for mounting a device to bodily tissue as recited in claim 38, wherein at least one of the first and second sutures is inserted in a curvilinear path.

45. A method for joining and holding closed for healing and regrowth an axial wound in a blood vessel such as an artery or vein, using a barbed suture including an elongated body, first and second sharp pointed distal ends for penetrating tissue, and a plurality of barbs extending from the periphery of the body, the barbs on a first portion of the body between the first end of the suture and a first axial location

on the body for permitting movement of the suture through the tissue in a direction of movement of the first end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the first end, and the barbs on a second portion of the body between the second end of the suture and a second axial location on the body which is less than the distance from the second end to the first axial location permitting movement of the suture through the tissue in a direction of movement of the second end and preventing movement of the suture relative to the tissue in a direction opposite the direction of movement of the second end, and using an insertion device, including a tubular element in which the suture is initially disposed, the insertion device having leading and trailing ends with openings therein with the first end of the suture proximate to the leading end, the method comprising the steps of:

- (a) inserting the first pointed end of the suture and the leading end of the insertion device through an entry point in the tissue spaced from and on one side of the wound;
- (b) pushing the first end of the suture and leading end of the insertion device through the tissue until the first end

of the suture and the leading end of the insertion device penetrate the blood vessel wall on one side of the wound, extend into the interior of the blood vessel, penetrate the blood vessel wall on the other side of the wound, and penetrate the tissue on the other side of the wound;

- (c) gripping and pulling the insertion device at the trailing end to remove the insertion device, leaving the suture in place; and

- (d) advancing the tissue on the two sides of the wound together as necessary to close the wound.

46. A method for joining and holding closed for healing and regrowth an axial wound in a blood vessel as recited in claim 45, further comprising the step of pushing the first end of the suture and the leading end of the insertion device through the tissue until the second axial location is disposed outside the blood vessel wall on one side of the wound and the first axial location is disposed outside the blood vessel wall on the other side of the wound, whereby there are no barbs disposed in the interior of the blood vessel.

摘要(译)

一种用于在身体组织中连接和保持闭合伤口，紧固伤口连接，捆绑伤口，将外来元件连接到组织，以及使用包括尖锐尖端的带倒勾的缝合线改变组织位置的方法。缝合线的每个末端包括倒钩，其允许在与缝合线另一端上的倒钩相反的方向上移动。这种双向倒刺缝合线用于本发明的方法，包括腹部外科手术，例如Nissen胃底折叠术，腹腔镜用途，例如稳定肠结构和进行膀胱造口术的封闭，肝脏与肠吻合术，关闭Zenker憩室的孔口，内窥镜用途，例如溃疡性病变的闭合或术后组织缺损，膀胱伤口闭合，瓣膜置换手术，器械附着，整容手术和血管伤口闭合。
