(57) **ABSTRACT**

Cannula anchor assemblies are disclosed which consist of a threaded cannula and a cannula anchor. The cannula anchor system allows for secure anchoring into the body wall, and proper cannula height adjustment prior to and during surgery. Sutures through the body wall may be secured to the cannula anchor either directly through the cannula anchor, or around suture posts attached therein. The cannula anchor also prevents excessive plunge of a trocar into the patient. The cannula anchor is generally configured with internal threads that mate with a threaded cannula.

## CANNULA ANCHOR

PRIORITY STATEMENT UNDER 35 U.S.C. §119  
& 37 C.F.R. §1.78

This application is a continuation of U.S. application Ser. No. 12/605,199 filed Oct. 23, 2009, which claims priority based upon prior U.S. Provisional Patent Application Ser. No. 61/107,870 filed Oct. 23, 2008 in the name of Michael T. Patton, Richard Mazzolla, Harrih Hasson, and Thane Blinman, entitled "Cannula With Adjustable Anchor," the disclosure of which is incorporated herein by reference.

### BACKGROUND OF THE INVENTION

Laparoscopy is a minimally invasive surgical procedure that utilizes a small tubular camera (laparoscope) to view abdominal and pelvic organs. During laparoscopy, devices called "trocars" are used to puncture the abdominal wall and provide access channels for the camera and thin laparoscopic surgical instruments. Since smaller incisions are made during these procedures, there is less patient trauma and reduced hospitalization. As a result, laparoscopy continues to grow in popularity.

A trocar assembly generally includes two major components, an obturator and a cannula. The obturator typically includes an elongate body having a sharpened distal tip. The sharp distal tip pierces and cuts the tissue forming the body wall. The cannula generally has a cylindrical configuration and a seal-valve housing. As the trocar is pushed or otherwise moved through the body wall, the sharp distal tip of the obturator functions to cut the tissue and provide an opening for the trocar. Once the trocar is operatively positioned, the obturator can be removed leaving the cannula to provide working access into the body cavity. For example, a laparoscope may be inserted through the cannula to view the body cavity or surgical instruments may be inserted through the cannula to perform ligations or other procedures.

The use of cannulas in laparoscopic surgery is well known. Once initial access to the abdominal cavity is attained, it is filled with carbon dioxide gas to allow for optimal viewing with the laparoscope and room for instrument manipulation. The cannula, which maintains the incision open to receive surgical instruments, must have a sealing mechanism that prevents or limits the escape of the gas when instruments of various diameters are inside. A valve mechanism prevents the escape of gas when instruments are removed from the cannula.

During the surgical procedure, it is desirable to secure or anchor the cannula position inside the incision (e.g., fascia) or in the skin to prevent movement of the cannula relative to the abdominal wall, and to prevent the cannula from slipping out of the incision, causing loss of insufflation pressure from the abdominal cavity. The present invention provides a novel cannula anchor assembly that overcomes deficiencies currently known in the art.

### SUMMARY OF THE INVENTION

The present invention provides an improved cannula and, more specifically, a cannula anchor system with cannula threads in combination with an internally threaded cannula anchor for use in a wide variety of surgical procedures and is intended to easily secure laparoscopic cannulas in the body wall to prevent accidental cannula slippage. It is generally directed towards a cannula that prevents a surgeon from having to re-insert the cannula one or more times during the

2

surgical procedure. While the cannula anchor system of the present invention is described herein for use with a surgical trocar, it is also well suited for a variety of other uses in which one apparatus is inserted and removed through an opening.

In one embodiment, the cannula anchor system consists of a threaded cannula and a single cannula anchor. The cannula anchor has internal threads, and its position on the cannula may be adjusted by rotating the cannula clockwise or counterclockwise. A suture can be threaded through the cannula anchor directly into body tissue to secure the cannula anchor system into place.

In an alternative embodiment, the cannula anchor can be constructed out of multiple materials to maximize its ability to be threaded up and down, and to be secured to the body tissue.

The foregoing has outlined rather broadly certain aspects of the present invention in order that the detailed description of the invention that follows may be better understood. Additional features and advantages of the invention will be described hereinafter which form the subject of the claims of the invention. It should be appreciated by those skilled in the art that the conception and specific embodiment disclosed may be readily utilized as a basis for modifying or designing other structures or processes for carrying out the same purposes of the present invention. It should also be realized by those skilled in the art that such equivalent constructions do not depart from the spirit and scope of the invention as set forth in the appended claims.

### DESCRIPTION OF THE DRAWINGS

A better understanding of the system and method of the present invention may be had by reference to the drawing figures, wherein:

FIG. 1 is a cross-sectional view of one embodiment of a cannula anchor system, illustrating a threaded cannula with a cannula anchor attached;

FIG. 2 is an isometric view of one embodiment of the cannula anchor system;

FIG. 3 shows another embodiment of the cannula anchor system;

FIG. 4 shows a cross-sectional view of another embodiment of the cannula anchor system;

FIG. 5A illustrates one embodiment of the cannula anchor system with the cannula anchor on the proximal portion of the cannula;

FIG. 5B illustrates one embodiment of the cannula anchor system with the cannula anchor on the distal portion of the cannula.

FIG. 6 illustrates three views of one embodiment of the cannula anchor.

### DESCRIPTION OF THE PREFERRED EMBODIMENTS

The present invention is an improved cannula anchor system to secure a cannula in the body wall during laparoscopic surgery. It should be appreciated that the present invention is equally applicable to any appropriate surgical procedure. References to surgical procedures and other terms used herein may be applicable to medical and veterinary surgery as well as other non-medical applications.

Referring now to the various figures of the drawing wherein like reference characters refer to like parts throughout the several views, FIG. 1 and FIG. 2 illustrate a cannula 101 in accordance with one preferred embodiment of the present invention. The cannula 101 is comprised of a cannula

body **102**, which houses the seal and valve, threaded cannula **103**, and cannula cap **104**. A cannula anchor **105** is shown assembled on the cannula threads **103**. The height of the cannula **101** can be adjusted by rotating the cannula **101** clockwise and counterclockwise, while holding the cannula anchor **105** steady. The cannula threads **103** mate with the internal threads on the cannula anchor **105**. The threads can be constructed in a clockwise or counterclockwise manner. The cannula anchor **105** may be secured into the body wall by suturing directly through the cannula anchor into the body wall. Alternatively, cannula anchor **105** may be constructed with one or more windows where sutures may be tied off. The cannula anchor **101** may be made of a variety of materials, including polymers, plastics, and metal. The cannula anchor **101** can also be used as a barrier to prevent excessive plunge of the trocar into the body cavity during insertion, or during instrument insertion through the cannula throughout the procedure.

FIG. **3** shows another embodiment of a cannula anchor system, illustrating a cannula **106** in combination with a cannula anchor **110**. In this embodiment, cannula **106** is comprised of cannula body **107**, cannula threads **108**, and cannula cap **109**.

FIG. **4** shows a cross-sectional view of the cannula anchor system illustrated in FIG. **3**. Cannula anchor **110** is shown comprised of two components, threaded cannula insert **111** and suture cone **112**. In this embodiment, the height of the cannula **106** can be adjusted by rotating the cannula **106** clockwise and counterclockwise, while holding the cannula anchor **110** steady. This embodiment provides the means to wrap suture around suture posts, as opposed to suturing directly through the cannula anchor material, when securing the cannula anchor system to the body.

FIG. **5A** shows the cannula anchor **105** in a proximal position on the cannula **101**. This position allows more of the cannula **101** to extend into the body. If less room is required inside the body cavity, cannula **101** can be rotated counterclockwise, thus moving the cannula anchor **105** to a more distal position on the cannula **101**.

FIG. **6** illustrates three views of the cannula anchor **105**. The cannula anchor internal threads **113** are illustrated in the isometric view. Finger grips **114** may be added to the cannula anchor to provide the surgeon more leverage when adjusting the height of the cannula.

While the present system and method has been disclosed according to the referred embodiment of the invention, those of ordinary skill in the art will understand that other embodiments have also been enabled. Even though the foregoing discussion has focused on particular embodiments, it is understood that other configurations are contemplated. In particular, even though the expressions “in one embodiment” or “in another embodiment” are used herein, these phrases are meant to generally reference embodiment possibilities and are not intended to limit the invention to those particular embodiment configurations. These terms may reference the same or different embodiments, and unless indicated otherwise, are combinable into aggregate embodiments. The terms “a”, “an” and “the” mean “one or more” unless expressly

specified otherwise. The term “connected” means “communicatively connected” unless otherwise defined.

When a single embodiment is described herein, it will be readily apparent that more than one embodiment may be used in place of a single embodiment. Similarly, where more than one embodiment is described herein, it will be readily apparent that a single embodiment may be substituted for that one device.

In light of the wide variety of possible seals available, the detailed embodiments are intended to be illustrative only and should not be taken as limiting the scope of the invention. Rather, what is claimed as the invention is all such modifications as may come within the spirit and scope of the following claims and equivalents thereto.

None of the description in this specification should be read as implying that any particular element, step or function is an essential element which must be included in the claim scope. The scope of the patented subject matter is defined only by the allowed claims and their equivalents. Unless explicitly recited, other aspects of the present invention as described in this specification do not limit the scope of the claims

What is claimed is:

1. A method of affixing a cannula to an abdominal wall comprising:

inserting an externally threaded cannula into an abdominal cavity of a patient during a laparoscopic surgical procedure, wherein internal threads of an anchor positioned around the cannula align with external threads of the cannula;

adjusting the anchor to abut the outside wall of the patient's abdomen by rotating the anchor relative to the cannula; securing the anchor to the outside of the patient's abdominal wall by passing sutures through an opening in the anchor and through a portion of the abdominal wall.

2. The method of claim 1, wherein the distance between the anchor and the outside wall of the patient's abdomen is adjustable after the anchor has been secured to the outside of the patient's abdominal wall by rotating the anchor relative to the cannula.

3. The method of claim 1, further including passing sutures through the opening in the anchor during the surgical procedure to close the opening in the abdominal cavity.

4. A method of affixing a suture cone to an abdominal wall comprising:

inserting an externally threaded cannula into an abdominal cavity of a patient during a laparoscopic surgical procedure, wherein an anchor is disposed around the cannula, the anchor having internal threads that align with external threads of the cannula, and wherein a suture cone is disposed around the cannula, the suture cone having one or more suture posts around which sutures may be wrapped during the surgical procedure;

adjusting the anchor to abut the outside wall of the patient's abdomen by rotating the anchor relative to the cannula; securing the suture cone, but not the anchor, to the outside wall of the patient's abdomen by passing sutures through an opening in the anchor and through a portion of the abdominal wall.

#### 摘要(译)

公开了一种套管锚固组件，其包括螺纹套管和套管锚固件。套管锚定系统允许牢固地锚固到体壁中，并且在手术之前和手术期间适当地调整套管高度。穿过体壁的缝合线可以直接通过套管锚固件或者连接在其中的缝合线柱固定到套管锚固件上。套管锚固件还防止套管针过度插入患者体内。套管锚通常配置有内螺纹，其与螺纹套管配合。
