A robotically controlled surgical tool comprising including a lockout mechanism is provided. The surgical tool may comprise an instrument mounting portion. The instrument mounting portion includes a housing, a plate, a shaft assembly comprising an end effector, and a coupler to couple the shaft assembly to the instrument mounting portion. The end effector comprises a first jaw member and a second jaw member, the first and second jaw members defining a channel therebetween, and a blade slideably receivable within the channel to cut tissue located between the first and second jaw members. The surgical tool may include an actuation mechanism to actuate the end effector to provide reciprocating movement of the blade within the channel. A lockout mechanism is coupled to the actuation mechanism. The lockout mechanism may selectively enable reciprocating movement of the blade. An interface mechanically and electrically couples the instrument mounting portion to a robotic manipulator.

BACKGROUND

[0011] The present disclosure relates generally to the field of robotic surgery. In particular, the present disclosure relates to, although not exclusively, robotically controlled surgical instruments. More particularly, the present disclosure relates to, although not exclusively, lockout mechanism for use with electrosurgical and ultrasonic robotic surgical instruments.

[0012] Ultrasonic surgical devices, such as ultrasonic scalpels, are used in many applications in surgical procedures by virtue of their unique performance characteristics. Depending upon specific device configurations and operational parameters, ultrasonic surgical devices can provide substantially simultaneous transection of tissue and homeostasis by coagulation, desirably minimizing patient trauma. An ultrasonic surgical device comprises a proximally-positioned ultrasonic transducer and an instrument coupled to the ultrasonic transducer having a distally-mounted end effector comprising an ultrasonic blade to cut and seal tissue. The end effector is typically coupled either to a handle and/or a robotic surgical implement via a shaft. The blade is acoustically coupled to the transducer via a waveguide extending through the shaft. Ultrasonic surgical devices of this nature can be configured for open surgical use, laparoscopic, or endoscopic surgical procedures including robotic-assisted procedures.

[0013] Ultrasonic energy cuts and coagulates tissue using temperatures lower than those used in electrosurgical procedures. Vibrating at high frequencies (e.g., 55,500 times per

second), the ultrasonic blade denatures protein in the tissue to form a sticky coagulum. Pressure exerted on tissue by the blade surface collapses blood vessels and allows the coagulum to form a haemostatic seal. A surgeon can control the cutting speed and coagulation by the force applied to the tissue by the end effector, the time over which the force is applied and the selected excursion level of the end effector.

[0014] Also used in many surgical applications are electrosurgical devices. Electrosurgical devices apply electrical energy to tissue in order to treat tissue. An electrosurgical device may comprise an instrument having a distally-mounted end effector comprising one or more electrodes. The end effector can be positioned against tissue such that electrical current is introduced into the tissue. Electrosurgical devices can be configured for bipolar or monopolar operation. During bipolar operation, current is introduced into and returned from the tissue by active and return electrodes, respectively, of the end effector. During monopolar operation, current is introduced into the tissue by an active electrode of the end effector and returned through a return electrode (e.g., a grounding pad) separately located on a patient's body. Heat generated by the current flow through the tissue may form hemostatic seals within the tissue and/or between tissues and thus may be particularly useful for sealing blood vessels, for example. The end effector of an electrosurgical device sometimes also comprises a cutting member that is movable relative to the tissue and the electrodes to transect the tissue.

[0015] Electrical energy applied by an electrosurgical device can be transmitted to the instrument by a generator. The electrical energy may be in the form of radio frequency ("RF") energy. RF energy is a form of electrical energy that may be in the frequency range of 300 kHz to 1 MHz. During its operation, an electrosurgical device can transmit low frequency RF energy through tissue, which causes ionic agitation, or friction, in effect resistive heating, thereby increasing the temperature of the tissue. Because a sharp boundary may be created between the affected tissue and the surrounding tissue, surgeons can operate with a high level of precision and control, without sacrificing un-targeted adjacent tissue. The low operating temperatures of RF energy may be useful for removing, shrinking, or sculpting soft tissue while simultaneously sealing blood vessels. RF energy may work particularly well on connective tissue, which is primarily comprised of collagen and shrinks when contacted by heat.

[0016] In many cases, it is desirable to prevent a cutting member from moving prior to the application of electrosurgical or ultrasonic energy to the blade element. In a robotic surgical system, a surgeon is typically not in the room with the patient and is unable to visually verify that energy has been applied to surgical instrument prior to activating the cutting member. It would be desirable to provide a mechanism for robotic surgical systems to prevent actuation of a cutting member prior to the application of electrosurgical or ultrasonic energy.

SUMMARY

[0017] In one embodiment, a robotically controlled surgical tool comprising including a lockout mechanism is provided. The surgical tool may comprise an instrument mounting portion. The instrument mounting portion includes a housing, a plate, a shaft assembly comprising an end effector, and a coupler to couple the shaft assembly to the instrument mounting portion. The end effector comprises a first jaw member and a second jaw member, the first and second jaw

members defining a channel therebetween, and a blade slideably receivable within the channel to cut tissue located between the first and second jaw members. The surgical tool may include an actuation mechanism to actuate the end effector to provide reciprocating movement of the blade within the channel. A lockout mechanism is coupled to the actuation mechanism. The lockout mechanism may selectively enable reciprocating movement of the blade. An interface mechanically and electrically couples the instrument mounting portion to a robotic manipulator.

BRIEF DESCRIPTION OF THE FIGURES

[0018] The features of the various embodiments are set forth with particularity in the appended claims. The various embodiments, however, both as to organization and methods of operation, together with advantages thereof, may best be understood by reference to the following description, taken in conjunction with the accompanying drawings as follows:

[0019] FIG. 1 illustrates one embodiment of a surgical system including a surgical instrument and an ultrasonic generator.

[0020] FIG. 2 illustrates one embodiment of the surgical instrument shown in FIG. 1.

[0021] FIG. 3 illustrates one embodiment of an ultrasonic end effector.

[0022] FIG. 4 illustrates another embodiment of an ultrasonic end effector.

[0023] FIG. 5 illustrates an exploded view of one embodiment of the surgical instrument shown in FIG. 1.

[0024] FIG. 6 illustrates a cut-away view of one embodiment of the surgical instrument shown in FIG. 1.

[0025] FIG. 7 illustrates various internal components of the surgical instrument shown in FIG. 1.

[0026] FIG. 8 illustrates a top view of one embodiment of a surgical system including a surgical instrument and an ultrasonic generator.

[0027] FIG. 9 illustrates one embodiment of a rotation assembly included in one example embodiment of the surgical instrument of FIG. 1.

[0028] FIG. 10 illustrates one embodiment of a surgical system including a surgical instrument having a single element end effector.

[0029] FIG. 11 is a perspective view of one embodiment of an electrical energy surgical instrument.

[0030] FIG. 12 is a side view of a handle of one embodiment of the surgical instrument of FIG. 1 with a half of a handle body removed to illustrate some of the components therein.

[0031] FIG. 13 illustrates a perspective view of one embodiment of the end effector of the surgical instrument of FIG. 11 with the jaws open and the distal end of an axially movable member in a retracted position.

[0032] FIG. 14 illustrates a perspective view of one embodiment of the end effector of the surgical instrument of FIG. 11 with the jaws closed and the distal end of an axially movable member in a partially advanced position.

[0033] FIG. 15 illustrates a perspective view of one embodiment of the axially moveable member of the surgical instrument of FIG. 11.

[0034] FIG. 16 illustrates a section view of one embodiment of the end effector of the surgical instrument of FIG. 11.

[0035] FIG. 17 illustrates a section a perspective view of one embodiment of a cordless electrical energy surgical instrument.

[0036] FIG. 18A illustrates a side view of a handle of one embodiment of the surgical instrument of FIG. 17 with a half handle body removed to illustrate various components therein.

[0037] FIG. 18B illustrates an RF drive and control circuit, according to one embodiment.

[0038] FIG. 18C illustrates the main components of the controller, according to one embodiment.

[0039] FIG. 19 illustrates a block diagram of one embodiment of a robotic surgical system.

[0040] FIG. 20 illustrates one embodiment of a robotic arm cart.

[0041] FIG. 21 illustrates one embodiment of the robotic manipulator of the robotic arm cart of FIG. 20.

[0042] FIG. 22 illustrates one embodiment of a robotic arm cart having an alternative set-up joint structure.

[0043] FIG. 23 illustrates one embodiment of a controller that may be used in conjunction with a robotic arm cart, such as the robotic arm carts of FIGS. 19-22.

[0044] FIG. 24 illustrates one embodiment of an ultrasonic surgical instrument adapted for use with a robotic system.

[0045] FIG. 25 illustrates one embodiment of an electro-surgical instrument adapted for use with a robotic system.

[0046] FIG. 26 illustrates one embodiment of an instrument drive assembly that may be coupled to surgical manipulators to receive and control the surgical instrument shown in FIG. 24.

[0047] FIG. 27 illustrates another view of the instrument drive assembly embodiment of FIG. 26 including the surgical instrument of FIG. 24.

[0048] FIG. 28 illustrates another view of the instrument drive assembly embodiment of FIG. 26 including the electro-surgical instrument of FIG. 25.

[0049] FIGS. 29-31 illustrate additional views of the adapter portion of the instrument drive assembly of FIG. 26.

[0050] FIGS. 32-34 illustrate one embodiment of the instrument mounting portion of FIGS. 24-25 showing components for translating motion of the driven elements into motion of the surgical instrument.

[0051] FIGS. 35-37 illustrate an alternate embodiment of the instrument mounting portion of FIGS. 24-25 showing an alternate example mechanism for translating rotation of the driven elements into rotational motion about the axis of the shaft and an alternate example mechanism for generating reciprocating translation of one or more members along the axis of the shaft 538.

[0052] FIGS. 38-42 illustrate an alternate embodiment of the instrument mounting portion FIGS. 24-25 showing another alternate example mechanism for translating rotation of the driven elements into rotational motion about the axis of the shaft.

[0053] FIGS. 43-46A illustrate an alternate embodiment of the instrument mounting portion showing an alternate example mechanism for differential translation of members along the axis of the shaft (e.g., for articulation).

[0054] FIGS. 46B-46C illustrate one embodiment of a tool mounting portion comprising internal power and energy sources.

[0055] FIG. 47 illustrates one embodiment of an instrument mounting portion comprising a lockout mechanism and an end-of-stroke switch.

[0056] FIG. 48 illustrates one embodiment of the lockout mechanism interfaced with a first gear and the end-of-stroke switch interfaced with a second gear.

[0057] FIG. 49 illustrates one embodiment of the lockout mechanism interfaced with a worm gear mounted to the shaft assembly.

DESCRIPTION

[0058] Various example embodiments are directed to a control system for a robotic surgical system.

[0059] Various embodiments of surgical instruments and robotic surgical systems are described herein. It will be understood by those skilled in the art that the various embodiments of the surgical tool lockout mechanism may be used with the described surgical instruments and robotic surgical systems. The descriptions are provided for example only, and those skilled in the art will understand that the disclosed surgical tool lockout mechanism is not limited to only the devices disclosed herein, but may be used with any compatible surgical instrument or robotic surgical system.

[0060] Reference will now be made in detail to several embodiments, including embodiments showing example implementations of robotic surgical instruments with end effectors comprising ultrasonic and/or electrosurgical elements. Wherever practicable similar or like reference numbers may be used in the figures and may indicate similar or like functionality. The figures depict example embodiments of the methods of use for purposes of illustration only. One skilled in the art will readily recognize from the following description that alternative example embodiments of the structures and methods illustrated herein may be employed without departing from the principles described herein.

[0061] FIG. 1 is a right side view of one embodiment of an ultrasonic surgical instrument 10. In the illustrated embodiment, the ultrasonic surgical instrument 10 may be employed in various surgical procedures including endoscopic or traditional open surgical procedures. In one example embodiment, the ultrasonic surgical instrument 10 comprises a handle assembly 12, an elongated shaft assembly 14, and an ultrasonic transducer 16. The handle assembly 12 comprises a trigger assembly 24, a distal rotation assembly 13, and a switch assembly 28. The elongated shaft assembly 14 comprises an end effector assembly 26, which comprises elements to dissect tissue or mutually grasp, cut, and coagulate vessels and/or tissue, and actuating elements to actuate the end effector assembly 26. The handle assembly 12 is adapted to receive the ultrasonic transducer 16 at the proximal end. The ultrasonic transducer 16 is mechanically engaged to the elongated shaft assembly 14 and portions of the end effector assembly 26. The ultrasonic transducer 16 is electrically coupled to a generator 20 via a cable 22. Although the majority of the drawings depict a multiple end effector assembly 26 for use in connection with laparoscopic surgical procedures, the ultrasonic surgical instrument 10 may be employed in more traditional open surgical procedures and in other embodiments, and may be configured for use in endoscopic procedures. For the purposes herein, the ultrasonic surgical instrument 10 is described in terms of an endoscopic instrument; however, it is contemplated that an open and/or laparoscopic version of the ultrasonic surgical instrument 10 also may include the same or similar operating components and features as described herein.

[0062] In various embodiments, the generator 20 comprises several functional elements, such as modules and/or blocks. Different functional elements or modules may be configured for driving different kinds of surgical devices. For example, an ultrasonic generator module 21 may drive an

ultrasonic device, such as the ultrasonic surgical instrument 10. In some example embodiments, the generator 20 also comprises an electrosurgery/RF generator module 23 for driving an electrosurgical device (or an electrosurgical embodiment of the ultrasonic surgical instrument 10). In various embodiments, the generator 20 may be formed integrally within the handle assembly 12. In such implementations, a battery would be co-located within the handle assembly 12 to act as the energy source. FIG. 18A and accompanying disclosures provide one example of such implementations.

[0063] In some embodiments, the electrosurgery/RF generator module 23 may be configured to generate a therapeutic and/or a sub-therapeutic energy level. In the example embodiment illustrated in FIG. 1, the generator 20 includes a control system 25 integral with the generator 20 and a foot switch 29 connected to the generator via a cable 27. The generator 20 may also comprise a triggering mechanism for activating a surgical instrument, such as the instrument 10. The triggering mechanism may include a power switch (not shown) as well as a foot switch 29. When activated by the foot switch 29, the generator 20 may provide energy to drive the acoustic assembly of the surgical instrument 10 and to drive the end effector 18 at a predetermined excursion level. The generator 20 drives or excites the acoustic assembly at any suitable resonant frequency of the acoustic assembly and/or derives the therapeutic/sub-therapeutic electromagnetic/RF energy.

[0064] In one embodiment, the electrosurgical/RF generator module 23 may be implemented as an electrosurgery unit (ESU) capable of supplying power sufficient to perform bipolar electrosurgery using radio frequency (RF) energy. In one embodiment, the ESU can be a bipolar ERBE ICC 350 sold by ERBE USA, Inc. of Marietta, Ga. In bipolar electrosurgery applications, as previously discussed, a surgical instrument having an active electrode and a return electrode can be utilized, wherein the active electrode and the return electrode can be positioned against, or adjacent to, the tissue to be treated such that current can flow from the active electrode to the return electrode through the tissue. Accordingly, the electrosurgical/RF module 23 generator may be configured for therapeutic purposes by applying electrical energy to the tissue T sufficient for treating the tissue (e.g., cauterization).

[0065] In one embodiment, the electrosurgical/RF generator module 23 may be configured to deliver a sub-therapeutic RF signal to implement a tissue impedance measurement module. In one embodiment, the electrosurgical/RF generator module 23 comprises a bipolar radio frequency generator as described in more detail below. In one embodiment, the electrosurgical/RF generator module 12 may be configured to monitor electrical impedance Z, of tissue T and to control the characteristics of time and power level based on the tissue T by way of a return electrode on provided on a clamp member of the end effector assembly 26. Accordingly, the electrosurgical/RF generator module 23 may be configured for sub-therapeutic purposes for measuring the impedance or other electrical characteristics of the tissue T. Techniques and circuit configurations for measuring the impedance or other electrical characteristics of tissue T are discussed in more detail in commonly assigned U.S. Patent Publication No. 2011/0015631, titled "Electrosurgical Generator for Ultrasonic Surgical Instruments," the disclosure of which is herein incorporated by reference in its entirety.

[0066] A suitable ultrasonic generator module 21 may be configured to functionally operate in a manner similar to the GEN300 sold by Ethicon Endo-Surgery, Inc. of Cincinnati,

Ohio as is disclosed in one or more of the following U.S. patents, all of which are incorporated by reference herein: U.S. Pat. No. 6,480,796 (Method for Improving the Start Up of an Ultrasonic System Under Zero Load Conditions); U.S. Pat. No. 6,537,291 (Method for Detecting Blade Breakage Using Rate and/or Impedance Information); U.S. Pat. No. 6,662,127 (Method for Detecting Presence of a Blade in an Ultrasonic System); U.S. Pat. No. 6,678,899 (Method for Detecting Transverse Vibrations in an Ultrasonic Surgical System); U.S. Pat. No. 6,977,495 (Detection Circuitry for Surgical Handpiece System); U.S. Pat. No. 7,077,853 (Method for Calculating Transducer Capacitance to Determine Transducer Temperature); U.S. Pat. No. 7,179,271 (Method for Driving an Ultrasonic System to Improve Acquisition of Blade Resonance Frequency at Startup); and U.S. Pat. No. 7,273,483 (Apparatus and Method for Alerting Generator Function in an Ultrasonic Surgical System).

[0067] It will be appreciated that in various embodiments, the generator **20** may be configured to operate in several modes. In one mode, the generator **20** may be configured such that the ultrasonic generator module **21** and the electrosurgical/RF generator module **23** may be operated independently.

[0068] For example, the ultrasonic generator module **21** may be activated to apply ultrasonic energy to the end effector assembly **26** and subsequently, either therapeutic sub-therapeutic RF energy may be applied to the end effector assembly **26** by the electrosurgical/RF generator module **23**. As previously discussed, the sub-therapeutic electrosurgical/RF energy may be applied to tissue clamped between claim elements of the end effector assembly **26** to measure tissue impedance to control the activation, or modify the activation, of the ultrasonic generator module **21**. Tissue impedance feedback from the application of the sub-therapeutic energy also may be employed to activate a therapeutic level of the electrosurgical/RF generator module **23** to seal the tissue (e.g., vessel) clamped between claim elements of the end effector assembly **26**.

[0069] In another embodiment, the ultrasonic generator module **21** and the electrosurgical/RF generator module **23** may be activated simultaneously. In one example, the ultrasonic generator module **21** is simultaneously activated with a sub-therapeutic RF energy level to measure tissue impedance simultaneously while the ultrasonic blade of the end effector assembly **26** cuts and coagulates the tissue (or vessel) clamped between the clamp elements of the end effector assembly **26**. Such feedback may be employed, for example, to modify the drive output of the ultrasonic generator module **21**. In another example, the ultrasonic generator module **21** may be driven simultaneously with electrosurgical/RF generator module **23** such that the ultrasonic blade portion of the end effector assembly **26** is employed for cutting the damaged tissue while the electrosurgical/RF energy is applied to electrode portions of the end effector clamp assembly **26** for sealing the tissue (or vessel).

[0070] When the generator **20** is activated via the triggering mechanism, electrical energy is continuously applied by the generator **20** to a transducer stack or assembly of the acoustic assembly. A phase-locked loop in the control system of the generator **20** may monitor feedback from the acoustic assembly. In another embodiment, electrical energy is intermittently applied (e.g., pulsed) by the generator **20**. The phase lock loop adjusts the frequency of the electrical energy sent by the generator **20** to match the resonant frequency of the selected longitudinal mode of vibration of the acoustic

assembly. In addition, a second feedback loop in the control system **25** maintains the electrical current supplied to the acoustic assembly at a pre-selected constant level in order to achieve substantially constant excursion at the end effector **18** of the acoustic assembly. In yet another embodiment, a third feedback loop in the control system **25** monitors impedance between electrodes located in the end effector assembly **26**. Although FIGS. 1-9 show a manually operated ultrasonic surgical instrument, it will be appreciated that ultrasonic surgical instruments may also be used in robotic applications, for example, as described herein, as well as combinations of manual robotic applications.

[0071] In ultrasonic operation mode, the electrical signal supplied to the acoustic assembly may cause the distal end of the end effector **18**, to vibrate longitudinally in the range of, for example, approximately 20 kHz to 250 kHz. According to various embodiments, the blade **22** may vibrate in the range of about 54 kHz to 56 kHz, for example, at about 55.5 kHz. In other embodiments, the blade **22** may vibrate at other frequencies including, for example, about 31 kHz or about 80 kHz. The excursion of the vibrations at the blade can be controlled by, for example, controlling the amplitude of the electrical signal applied to the transducer assembly of the acoustic assembly by the generator **20**. As noted above, the triggering mechanism of the generator **20** allows a user to activate the generator **20** so that electrical energy may be continuously or intermittently supplied to the acoustic assembly. The generator **20** also has a power line for insertion in an electro-surgical unit or conventional electrical outlet. It is contemplated that the generator **20** can also be powered by a direct current (DC) source, such as a battery. The generator **20** can comprise any suitable generator, such as Model No. GEN04, and/or Model No. GEN11 available from Ethicon Endo-Surgery, Inc.

[0072] FIG. 2 is a left perspective view of one example embodiment of the ultrasonic surgical instrument **10** showing the handle assembly **12**, the distal rotation assembly **13**, the elongated shaft assembly **14**, and the end effector assembly **26**. In the illustrated embodiment the elongated shaft assembly **14** comprises a distal end **52** dimensioned to mechanically engage the end effector assembly **26** and a proximal end **50** that mechanically engages the handle assembly **12** and the distal rotation assembly **13**. The proximal end **50** of the elongated shaft assembly **14** is received within the handle assembly **12** and the distal rotation assembly **13**. More details relating to the connections between the elongated endoscopic shaft assembly **14**, the handle assembly **12**, and the distal rotation assembly **13** are provided in the description of FIGS. 5 and 7.

[0073] In the illustrated embodiment, the trigger assembly **24** comprises a trigger **32** that operates in conjunction with a fixed handle **34**. The fixed handle **34** and the trigger **32** are ergonomically formed and adapted to interface comfortably with the user. The fixed handle **34** is integrally associated with the handle assembly **12**. The trigger **32** is pivotally movable relative to the fixed handle **34** as explained in more detail below with respect to the operation of the ultrasonic surgical instrument **10**. The trigger **32** is pivotally movable in direction **33A** toward the fixed handle **34** when the user applies a squeezing force against the trigger **32**. A spring element **98** (FIG. 5) causes the trigger **32** to pivotally move in direction **33B** when the user releases the squeezing force against the trigger **32**.

[0074] In one example embodiment, the trigger 32 comprises an elongated trigger hook 36, which defines an aperture 38 between the elongated trigger hook 36 and the trigger 32. The aperture 38 is suitably sized to receive one or multiple fingers of the user therethrough. The trigger 32 also may comprise a resilient portion 32a molded over the trigger 32 substrate. The overmolded resilient portion 32a is formed to provide a more comfortable contact surface for control of the trigger 32 in outward direction 33B. In one example embodiment, the overmolded resilient portion 32a may be provided over a portion of the elongated trigger hook 36. The proximal surface of the elongated trigger hook 32 remains uncoated or coated with a non-resilient substrate to enable the user to easily slide their fingers in and out of the aperture 38. In another embodiment, the geometry of the trigger forms a fully closed loop which defines an aperture suitably sized to receive one or multiple fingers of the user therethrough. The fully closed loop trigger also may comprise a resilient portion molded over the trigger substrate.

[0075] In one example embodiment, the fixed handle 34 comprises a proximal contact surface 40 and a grip anchor or saddle surface 42. The saddle surface 42 rests on the web where the thumb and the index finger are joined on the hand. The proximal contact surface 40 has a pistol grip contour that receives the palm of the hand in a normal pistol grip with no rings or apertures. The profile curve of the proximal contact surface 40 may be contoured to accommodate or receive the palm of the hand. A stabilization tail 44 is located towards a more proximal portion of the handle assembly 12. The stabilization tail 44 may be in contact with the uppermost web portion of the hand located between the thumb and the index finger to stabilize the handle assembly 12 and make the handle assembly 12 more controllable.

[0076] In one example embodiment, the switch assembly 28 may comprise a toggle switch 30. The toggle switch 30 may be implemented as a single component with a central pivot 30a located within inside the handle assembly 12 to eliminate the possibility of simultaneous activation. In one example embodiment, the toggle switch 30 comprises a first projecting knob 30a and a second projecting knob 30b to set the power setting of the ultrasonic transducer 16 between a minimum power level (e.g., MIN) and a maximum power level (e.g., MAX). In another embodiment, the rocker switch may pivot between a standard setting and a special setting. The special setting may allow one or more special programs to be implemented by the device. The toggle switch 30 rotates about the central pivot as the first projecting knob 30a and the second projecting knob 30b are actuated. The one or more projecting knobs 30a, 30b are coupled to one or more arms that move through a small arc and cause electrical contacts to close or open an electric circuit to electrically energize or de-energize the ultrasonic transducer 16 in accordance with the activation of the first or second projecting knobs 30a, 30b. The toggle switch 30 is coupled to the generator 20 to control the activation of the ultrasonic transducer 16. The toggle switch 30 comprises one or more electrical power setting switches to activate the ultrasonic transducer 16 to set one or more power settings for the ultrasonic transducer 16. The forces required to activate the toggle switch 30 are directed substantially toward the saddle point 42, thus avoiding any tendency of the instrument to rotate in the hand when the toggle switch 30 is activated.

[0077] In one example embodiment, the first and second projecting knobs 30a, 30b are located on the distal end of the

handle assembly 12 such that they can be easily accessible by the user to activate the power with minimal, or substantially no, repositioning of the hand grip, making it suitable to maintain control and keep attention focused on the surgical site (e.g., a monitor in a laparoscopic procedure) while activating the toggle switch 30. The projecting knobs 30a, 30b may be configured to wrap around the side of the handle assembly 12 to some extent to be more easily accessible by variable finger lengths and to allow greater freedom of access to activation in awkward positions or for shorter fingers.

[0078] In the illustrated embodiment, the first projecting knob 30a comprises a plurality of tactile elements 30c, e.g., textured projections or “bumps” in the illustrated embodiment, to allow the user to differentiate the first projecting knob 30a (MAX) from the second projecting knob 30b (MIN). It will be appreciated by those skilled in the art that several ergonomic features may be incorporated into the handle assembly 12. Such ergonomic features are described in U.S. Pat. App. Pub. No. 2009/0105750 entitled “Ergonomic Surgical Instruments” which is incorporated by reference herein in its entirety.

[0079] In one example embodiment, the toggle switch 30 may be operated by the hand of the user. The user may easily access the first and second projecting knobs 30a, 30b at any point while also avoiding inadvertent or unintentional activation at any time. The toggle switch 30 may readily operated with a finger to control the power to the ultrasonic assembly 16 and/or to the ultrasonic assembly 16. For example, the index finger may be employed to activate the first contact portion 30a to turn on the ultrasonic assembly 16 to a maximum (MAX) power level. The index finger may be employed to activate the second contact portion 30b to turn on the ultrasonic assembly 16 to a minimum (MIN) power level. In another embodiment, the rocker switch may pivot the instrument 10 between a standard setting and a special setting. The special setting may allow one or more special programs to be implemented by the instrument 10. The toggle switch 30 may be operated without the user having to look at the first or second projecting knob 30a, 30b. For example, the first projecting knob 30a or the second projecting knob 30b may comprise a texture or projections to tactilely differentiate between the first and second projecting knobs 30a, 30b without looking.

[0080] In other embodiments, the trigger 32 and/or the toggle switch 30 may be employed to actuate the electrosurgical/RF module 23 individually or in combination with activation of the ultrasonic generator module 21.

[0081] In one example embodiment, the distal rotation assembly 13 is rotatable without limitation in either direction about a longitudinal axis “T.” The distal rotation assembly 13 is mechanically engaged to the elongated shaft assembly 14. The distal rotation assembly 13 is located on a distal end of the handle assembly 12. The distal rotation assembly 13 comprises a cylindrical hub 46 and a rotation knob 48 formed over the hub 46. The hub 46 mechanically engages the elongated shaft assembly 14. The rotation knob 48 may comprise fluted polymeric features and may be engaged by a finger (e.g., an index finger) to rotate the elongated shaft assembly 14. The hub 46 may comprise a material molded over the primary structure to form the rotation knob 48. The rotation knob 48 may be overmolded over the hub 46. The hub 46 comprises an end cap portion 46a that is exposed at the distal end. The end cap portion 46a of the hub 46 may contact the surface of a trocar during laparoscopic procedures. The hub 46 may be

formed of a hard durable plastic such as polycarbonate to alleviate any friction that may occur between the end cap portion **46a** and the trocar. The rotation knob **48** may comprise “scallops” or flutes formed of raised ribs **48a** and concave portions **48b** located between the ribs **48a** to provide a more precise rotational grip. In one example embodiment, the rotation knob **48** may comprise a plurality of flutes (e.g., three or more flutes). In other embodiments, any suitable number of flutes may be employed. The rotation knob **48** may be formed of a softer polymeric material overmolded onto the hard plastic material. For example, the rotation knob **48** may be formed of pliable, resilient, flexible polymeric materials including Versaflex® TPE alloys made by GLS Corporation, for example. This softer overmolded material may provide a greater grip and more precise control of the movement of the rotation knob **48**. It will be appreciated that any materials that provide adequate resistance to sterilization, are biocompatible, and provide adequate frictional resistance to surgical gloves may be employed to form the rotation knob **48**.

[0082] In one example embodiment, the handle assembly **12** is formed from two (2) housing portions or shrouds comprising a first portion **12a** and a second portion **12b**. From the perspective of a user viewing the handle assembly **12** from the distal end towards the proximal end, the first portion **12a** is considered the right portion and the second portion **12b** is considered the left portion. Each of the first and second portions **12a**, **12b** includes a plurality of interfaces **69** (FIG. 5) dimensioned to mechanically align and engage each another to form the handle assembly **12** and enclosing the internal working components thereof. The fixed handle **34**, which is integrally associated with the handle assembly **12**, takes shape upon the assembly of the first and second portions **12a** and **12b** of the handle assembly **12**. A plurality of additional interfaces (not shown) may be disposed at various points around the periphery of the first and second portions **12a** and **12b** of the handle assembly **12** for ultrasonic welding purposes, e.g., energy direction/deflection points. The first and second portions **12a** and **12b** (as well as the other components described below) may be assembled together in any fashion known in the art. For example, alignment pins, snap-like interfaces, tongue and groove interfaces, locking tabs, adhesive ports, may all be utilized either alone or in combination for assembly purposes.

[0083] In one example embodiment, the elongated shaft assembly **14** comprises a proximal end **50** adapted to mechanically engage the handle assembly **12** and the distal rotation assembly **13**; and a distal end **52** adapted to mechanically engage the end effector assembly **26**. The elongated shaft assembly **14** comprises an outer tubular sheath **56** and a reciprocating tubular actuating member **58** located within the outer tubular sheath **56**. The proximal end of the tubular reciprocating tubular actuating member **58** is mechanically engaged to the trigger **32** of the handle assembly **12** to move in either direction **60A** or **60B** in response to the actuation and/or release of the trigger **32**. The pivotably moveable trigger **32** may generate reciprocating motion along the longitudinal axis “T.” Such motion may be used, for example, to actuate the jaws or clamping mechanism of the end effector assembly **26**. A series of linkages translate the pivotal rotation of the trigger **32** to axial movement of a yoke coupled to an actuation mechanism, which controls the opening and closing of the jaws of the clamping mechanism of the end effector assembly **26**. The distal end of the tubular reciprocating tubular actuating member **58** is mechanically engaged to the end

effector assembly **26**. In the illustrated embodiment, the distal end of the tubular reciprocating tubular actuating member **58** is mechanically engaged to a clamp arm assembly **64**, which is pivotable about a pivot point **70**, to open and close the clamp arm assembly **64** in response to the actuation and/or release of the trigger **32**. For example, in the illustrated embodiment, the clamp arm assembly **64** is movable in direction **62A** from an open position to a closed position about a pivot point **70** when the trigger **32** is squeezed in direction **33A**. The clamp arm assembly **64** is movable in direction **62B** from a closed position to an open position about the pivot point **70** when the trigger **32** is released or outwardly contacted in direction **33B**.

[0084] In one example embodiment, the end effector assembly **26** is attached at the distal end **52** of the elongated shaft assembly **14** and includes a clamp arm assembly **64** and a blade **66**. The jaws of the clamping mechanism of the end effector assembly **26** are formed by clamp arm assembly **64** and the blade **66**. The blade **66** is ultrasonically actuatable and is acoustically coupled to the ultrasonic transducer **16**. The trigger **32** on the handle assembly **12** is ultimately connected to a drive assembly, which together, mechanically cooperate to effect movement of the clamp arm assembly **64**. Squeezing the trigger **32** in direction **33A** moves the clamp arm assembly **64** in direction **62A** from an open position, wherein the clamp arm assembly **64** and the blade **66** are disposed in a spaced relation relative to one another, to a clamped or closed position, wherein the clamp arm assembly **64** and the blade **66** cooperate to grasp tissue therebetween. The clamp arm assembly **64** may comprise a clamp pad **69** to engage tissue between the blade **66** and the clamp arm **64**. Releasing the trigger **32** in direction **33B** moves the clamp arm assembly **64** in direction **62B** from a closed relationship, to an open position, wherein the clamp arm assembly **64** and the blade **66** are disposed in a spaced relation relative to one another.

[0085] The proximal portion of the handle assembly **12** comprises a proximal opening **68** to receive the distal end of the ultrasonic assembly **16**. The ultrasonic assembly **16** is inserted in the proximal opening **68** and is mechanically engaged to the elongated endoscopic shaft assembly **14**.

[0086] In one example embodiment, the elongated trigger hook **36** portion of the trigger **32** provides a longer trigger lever with a shorter span and rotation travel. The longer lever of the elongated trigger hook **36** allows the user to employ multiple fingers within the aperture **38** to operate the elongated trigger hook **36** and cause the trigger **32** to pivot in direction **33B** to open the jaws of the end effector assembly **26**. For example, the user may insert three fingers (e.g., the middle, ring, and little fingers) in the aperture **38**. Multiple fingers allows the surgeon to exert higher input forces on the trigger **32** and the elongated trigger hook **36** to activate the end effector assembly **26**. The shorter span and rotation travel creates a more comfortable grip when closing or squeezing the trigger **32** in direction **33A** or when opening the trigger **32** in the outward opening motion in direction **33B** lessening the need to extend the fingers further outward. This substantially lessens hand fatigue and strain associated with the outward opening motion of the trigger **32** in direction **33B**. The outward opening motion of the trigger may be spring-assisted by spring element **98** (FIG. 5) to help alleviate fatigue. The opening spring force is sufficient to assist the ease of opening, but not strong enough to adversely impact the tactile feedback of tissue tension during spreading dissection.

[0087] For example, during a surgical procedure either the index finger may be used to control the rotation of the elongated shaft assembly 14 to locate the jaws of the end effector assembly 26 in a suitable orientation. The middle and/or the other lower fingers may be used to squeeze the trigger 32 and grasp tissue within the jaws. Once the jaws are located in the desired position and the jaws are clamped against the tissue, the index finger can be used to activate the toggle switch 30 to adjust the power level of the ultrasonic transducer 16 to treat the tissue. Once the tissue has been treated, the user may release the trigger 32 by pushing outwardly in the distal direction against the elongated trigger hook 36 with the middle and/or lower fingers to open the jaws of the end effector assembly 26. This basic procedure may be performed without the user having to adjust their grip of the handle assembly 12.

[0088] FIGS. 3-4 illustrate the connection of the elongated endoscopic shaft assembly 14 relative to the end effector assembly 26. As previously described, in the illustrated embodiment, the end effector assembly 26 comprises a clamp arm assembly 64 and a blade 66 to form the jaws of the clamping mechanism. The blade 66 may be an ultrasonically actuatable blade acoustically coupled to the ultrasonic transducer 16. The trigger 32 is mechanically connected to a drive assembly. Together, the trigger 32 and the drive assembly mechanically cooperate to move the clamp arm assembly 64A to an open position in direction 62B wherein the clamp arm assembly 64 and the blade 66 are disposed in spaced relation relative to one another, to a clamped or closed position in direction 62B wherein the clamp arm assembly 64 and the blade 66 cooperate to grasp tissue therebetween. The clamp arm assembly 64 may comprise a clamp pad 69 to engage tissue between the blade 66 and the clamp arm 64. The distal end of the tubular reciprocating tubular actuating member 58 is mechanically engaged to the end effector assembly 26. In the illustrated embodiment, the distal end of the tubular reciprocating tubular actuating member 58 is mechanically engaged to the clamp arm assembly 64, which is pivotable about the pivot point 70, to open and close the clamp arm assembly 64 in response to the actuation and/or release of the trigger 32. For example, in the illustrated embodiment, the clamp arm assembly 64 is movable from an open position to a closed position in direction 62B about a pivot point 70 when the trigger 32 is squeezed in direction 33A. The clamp arm assembly 64 is movable from a closed position to an open position in direction 62A about the pivot point 70 when the trigger 32 is released or outwardly contacted in direction 33B.

[0089] As previously discussed, the clamp arm assembly 64 may comprise electrodes electrically coupled to the electrosurgical/RF generator module 23 to receive therapeutic and/or sub-therapeutic energy, where the electrosurgical/RF energy may be applied to the electrodes either simultaneously or non-simultaneously with the ultrasonic energy being applied to the blade 66. Such energy activations may be applied in any suitable combinations to achieve a desired tissue effect in cooperation with an algorithm or other control logic.

[0090] FIG. 5 is an exploded view of the ultrasonic surgical instrument 10 shown in FIG. 2. In the illustrated embodiment, the exploded view shows the internal elements of the handle assembly 12, the handle assembly 12, the distal rotation assembly 13, the switch assembly 28, and the elongated endoscopic shaft assembly 14. In the illustrated embodiment, the first and second portions 12a, 12b mate to form the handle

assembly 12. The first and second portions 12a, 12b each comprises a plurality of interfaces 69 dimensioned to mechanically align and engage one another to form the handle assembly 12 and enclose the internal working components of the ultrasonic surgical instrument 10. The rotation knob 48 is mechanically engaged to the outer tubular sheath 56 so that it may be rotated in circular direction 54 up to 360°. The outer tubular sheath 56 is located over the reciprocating tubular actuating member 58, which is mechanically engaged to and retained within the handle assembly 12 via a plurality of coupling elements 72. The coupling elements 72 may comprise an O-ring 72a, a tube collar cap 72b, a distal washer 72c, a proximal washer 72d, and a thread tube collar 72e. The reciprocating tubular actuating member 58 is located within a reciprocating yoke 84, which is retained between the first and second portions 12a, 12b of the handle assembly 12. The yoke 84 is part of a reciprocating yoke assembly 88. A series of linkages translate the pivotal rotation of the elongated trigger hook 32 to the axial movement of the reciprocating yoke 84, which controls the opening and closing of the jaws of the clamping mechanism of the end effector assembly 26 at the distal end of the ultrasonic surgical instrument 10. In one example embodiment, a four-link design provides mechanical advantage in a relatively short rotation span, for example.

[0091] In one example embodiment, an ultrasonic transmission waveguide 78 is disposed inside the reciprocating tubular actuating member 58. The distal end 52 of the ultrasonic transmission waveguide 78 is acoustically coupled (e.g., directly or indirectly mechanically coupled) to the blade 66 and the proximal end 50 of the ultrasonic transmission waveguide 78 is received within the handle assembly 12. The proximal end 50 of the ultrasonic transmission waveguide 78 is adapted to acoustically couple to the distal end of the ultrasonic transducer 16 as discussed in more detail below. The ultrasonic transmission waveguide 78 is isolated from the other elements of the elongated shaft assembly 14 by a protective sheath 80 and a plurality of isolation elements 82, such as silicone rings. The outer tubular sheath 56, the reciprocating tubular actuating member 58, and the ultrasonic transmission waveguide 78 are mechanically engaged by a pin 74. The switch assembly 28 comprises the toggle switch 30 and electrical elements 86a,b to electrically energize the ultrasonic transducer 16 in accordance with the activation of the first or second projecting knobs 30a, 30b.

[0092] In one example embodiment, the outer tubular sheath 56 isolates the user or the patient from the ultrasonic vibrations of the ultrasonic transmission waveguide 78. The outer tubular sheath 56 generally includes a hub 76. The outer tubular sheath 56 is threaded onto the distal end of the handle assembly 12. The ultrasonic transmission waveguide 78 extends through the opening of the outer tubular sheath 56 and the isolation elements 82 isolate the ultrasonic transmission waveguide 78 from the outer tubular sheath 56. The outer tubular sheath 56 may be attached to the waveguide 78 with the pin 74. The hole to receive the pin 74 in the waveguide 78 may occur nominally at a displacement node. The waveguide 78 may screw or snap into the hand piece handle assembly 12 by a stud. Flat portions on the hub 76 may allow the assembly to be torqued to a required level. In one example embodiment, the hub 76 portion of the outer tubular sheath 56 is preferably constructed from plastic and the tubular elongated portion of the outer tubular sheath 56 is fabricated from stainless steel.

Alternatively, the ultrasonic transmission waveguide **78** may comprise polymeric material surrounding it to isolate it from outside contact.

[0093] In one example embodiment, the distal end of the ultrasonic transmission waveguide **78** may be coupled to the proximal end of the blade **66** by an internal threaded connection, preferably at or near an antinode. It is contemplated that the blade **66** may be attached to the ultrasonic transmission waveguide **78** by any suitable means, such as a welded joint or the like. Although the blade **66** may be detachable from the ultrasonic transmission waveguide **78**, it is also contemplated that the single element end effector (e.g., the blade **66**) and the ultrasonic transmission waveguide **78** may be formed as a single unitary piece.

[0094] In one example embodiment, the trigger **32** is coupled to a linkage mechanism to translate the rotational motion of the trigger **32** in directions **33A** and **33B** to the linear motion of the reciprocating tubular actuating member **58** in corresponding directions **60A** and **60B**. The trigger **32** comprises a first set of flanges **98** with openings formed therein to receive a first yoke pin **92a**. The first yoke pin **92a** is also located through a set of openings formed at the distal end of the yoke **84**. The trigger **32** also comprises a second set of flanges **96** to receive a first end **92a** of a link **92**. A trigger pin **90** is received in openings formed in the link **92** and the second set of flanges **96**. The trigger pin **90** is received in the openings formed in the link **92** and the second set of flanges **96** and is adapted to couple to the first and second portions **12a**, **12b** of the handle assembly **12** to form a trigger pivot point for the trigger **32**. A second end **92b** of the link **92** is received in a slot **384** formed in a proximal end of the yoke **84** and is retained therein by a second yoke pin **94b**. As the trigger **32** is pivotally rotated about the pivot point **190** formed by the trigger pin **90**, the yoke translates horizontally along longitudinal axis “T” in a direction indicated by arrows **60A,B**.

[0095] FIG. 8 illustrates one example embodiment of an ultrasonic surgical instrument **10**. In the illustrated embodiment, a cross-sectional view of the ultrasonic transducer **16** is shown within a partial cutaway view of the handle assembly **12**. One example embodiment of the ultrasonic surgical instrument **10** comprises the ultrasonic signal generator **20** coupled to the ultrasonic transducer **16**, comprising a hand piece housing **99**, and an ultrasonically actuatable single or multiple element end effector assembly **26**. As previously discussed, the end effector assembly **26** comprises the ultrasonically actuatable blade **66** and the clamp arm **64**. The ultrasonic transducer **16**, which is known as a “Langevin stack”, generally includes a transduction portion **100**, a first resonator portion or end-bell **102**, and a second resonator portion or fore-bell **104**, and ancillary components. The total construction of these components is a resonator. The ultrasonic transducer **16** is preferably an integral number of one-half system wavelengths ($n\lambda/2$; where “n” is any positive integer; e.g., $n=1, 2, 3 \dots$) in length as will be described in more detail later. An acoustic assembly **106** includes the ultrasonic transducer **16**, a nose cone **108**, a velocity transformer **118**, and a surface **110**.

[0096] In one example embodiment, the distal end of the end-bell **102** is connected to the proximal end of the transduction portion **100**, and the proximal end of the fore-bell **104** is connected to the distal end of the transduction portion **100**. The fore-bell **104** and the end-bell **102** have a length determined by a number of variables, including the thickness of the

transduction portion **100**, the density and modulus of elasticity of the material used to manufacture the end-bell **102** and the fore-bell **22**, and the resonant frequency of the ultrasonic transducer **16**. The fore-bell **104** may be tapered inwardly from its proximal end to its distal end to amplify the ultrasonic vibration amplitude as the velocity transformer **118**, or alternately may have no amplification. A suitable vibrational frequency range may be about 20 Hz to 32 kHz and a well-suited vibrational frequency range may be about 30-10 kHz. A suitable operational vibrational frequency may be approximately 55.5 kHz, for example.

[0097] In one example embodiment, the piezoelectric elements **112** may be fabricated from any suitable material, such as, for example, lead zirconate-titanate, lead meta-niobate, lead titanate, barium titanate, or other piezoelectric ceramic material. Each of positive electrodes **114**, negative electrodes **116**, and the piezoelectric elements **112** has a bore extending through the center. The positive and negative electrodes **114** and **116** are electrically coupled to wires **120** and **122**, respectively. The wires **120** and **122** are encased within the cable **22** and electrically connectable to the ultrasonic signal generator **20**.

[0098] The ultrasonic transducer **16** of the acoustic assembly **106** converts the electrical signal from the ultrasonic signal generator **20** into mechanical energy that results in primarily a standing acoustic wave of longitudinal vibratory motion of the ultrasonic transducer **16** and the blade **66** portion of the end effector assembly **26** at ultrasonic frequencies. In another embodiment, the vibratory motion of the ultrasonic transducer may act in a different direction. For example, the vibratory motion may comprise a local longitudinal component of a more complicated motion of the tip of the elongated shaft assembly **14**. A suitable generator is available as model number GEN11, from Ethicon Endo-Surgery, Inc., Cincinnati, Ohio. When the acoustic assembly **106** is energized, a vibratory motion standing wave is generated through the acoustic assembly **106**. The ultrasonic surgical instrument **10** is designed to operate at a resonance such that an acoustic standing wave pattern of predetermined amplitude is produced. The amplitude of the vibratory motion at any point along the acoustic assembly **106** depends upon the location along the acoustic assembly **106** at which the vibratory motion is measured. A minimum or zero crossing in the vibratory motion standing wave is generally referred to as a node (i.e., where motion is minimal), and a local absolute value maximum or peak in the standing wave is generally referred to as an anti-node (i.e., where local motion is maximal). The distance between an anti-node and its nearest node is one-quarter wavelength ($\lambda/4$).

[0099] The wires **120** and **122** transmit an electrical signal from the ultrasonic signal generator **20** to the positive electrodes **114** and the negative electrodes **116**. The piezoelectric elements **112** are energized by the electrical signal supplied from the ultrasonic signal generator **20** in response to an actuator **224**, such as a foot switch, for example, to produce an acoustic standing wave in the acoustic assembly **106**. The electrical signal causes disturbances in the piezoelectric elements **112** in the form of repeated small displacements resulting in large alternating compression and tension forces within the material. The repeated small displacements cause the piezoelectric elements **112** to expand and contract in a continuous manner along the axis of the voltage gradient, producing longitudinal waves of ultrasonic energy. The ultrasonic energy is transmitted through the acoustic assembly

106 to the blade 66 portion of the end effector assembly 26 via a transmission component or an ultrasonic transmission waveguide portion 78 of the elongated shaft assembly 14.

[0100] In one example embodiment, in order for the acoustic assembly 106 to deliver energy to the blade 66 portion of the end effector assembly 26, all components of the acoustic assembly 106 must be acoustically coupled to the blade 66. The distal end of the ultrasonic transducer 16 may be acoustically coupled at the surface 110 to the proximal end of the ultrasonic transmission waveguide 78 by a threaded connection such as a stud 124.

[0101] In one example embodiment, the components of the acoustic assembly 106 are preferably acoustically tuned such that the length of any assembly is an integral number of one-half wavelengths ($n\lambda/2$), where the wavelength λ is the wavelength of a pre-selected or operating longitudinal vibration drive frequency f_d of the acoustic assembly 106. It is also contemplated that the acoustic assembly 106 may incorporate any suitable arrangement of acoustic elements.

[0102] In one example embodiment, the blade 66 may have a length substantially equal to an integral multiple of one-half system wavelengths ($n\lambda/2$). A distal end of the blade 66 may be disposed near an antinode in order to provide the maximum longitudinal excursion of the distal end. When the transducer assembly is energized, the distal end of the blade 66 may be configured to move in the range of, for example, approximately 10 to 500 microns peak-to-peak, and preferably in the range of about 30 to 64 microns at a predetermined vibrational frequency of 55 kHz, for example.

[0103] In one example embodiment, the blade 66 may be coupled to the ultrasonic transmission waveguide 78. The blade 66 and the ultrasonic transmission waveguide 78 as illustrated are formed as a single unit construction from a material suitable for transmission of ultrasonic energy. Examples of such materials include Ti6Al4V (an alloy of Titanium including Aluminum and Vanadium), Aluminum, Stainless Steel, or other suitable materials. Alternately, the blade 66 may be separable (and of differing composition) from the ultrasonic transmission waveguide 78, and coupled by, for example, a stud, weld, glue, quick connect, or other suitable known methods. The length of the ultrasonic transmission waveguide 78 may be substantially equal to an integral number of one-half wavelengths ($n\lambda/2$), for example. The ultrasonic transmission waveguide 78 may be preferably fabricated from a solid core shaft constructed out of material suitable to propagate ultrasonic energy efficiently, such as the titanium alloy discussed above (i.e., Ti6Al4V) or any suitable aluminum alloy, or other alloys, for example.

[0104] In one example embodiment, the ultrasonic transmission waveguide 78 comprises a longitudinally projecting attachment post at a proximal end to couple to the surface 110 of the ultrasonic transmission waveguide 78 by a threaded connection such as the stud 124. The ultrasonic transmission waveguide 78 may include a plurality of stabilizing silicone rings or compliant supports 82 (FIG. 5) positioned at a plurality of nodes. The silicone rings 82 dampen undesirable vibration and isolate the ultrasonic energy from an outer protective sheath 80 (FIG. 5) assuring the flow of ultrasonic energy in a longitudinal direction to the distal end of the blade 66 with maximum efficiency.

[0105] FIG. 9 illustrates one example embodiment of the proximal rotation assembly 128. In the illustrated embodiment, the proximal rotation assembly 128 comprises the proximal rotation knob 134 inserted over the cylindrical hub

135. The proximal rotation knob 134 comprises a plurality of radial projections 138 that are received in corresponding slots 130 formed on a proximal end of the cylindrical hub 135. The proximal rotation knob 134 defines an opening 142 to receive the distal end of the ultrasonic transducer 16. The radial projections 138 are formed of a soft polymeric material and define a diameter that is undersized relative to the outside diameter of the ultrasonic transducer 16 to create a friction interference fit when the distal end of the ultrasonic transducer 16. The polymeric radial projections 138 protrude radially into the opening 142 to form "gripper" ribs that firmly grip the exterior housing of the ultrasonic transducer 16. Therefore, the proximal rotation knob 134 securely grips the ultrasonic transducer 16.

[0106] The distal end of the cylindrical hub 135 comprises a circumferential lip 132 and a circumferential bearing surface 140. The circumferential lip engages a groove formed in the housing 12 and the circumferential bearing surface 140 engages the housing 12. Thus, the cylindrical hub 135 is mechanically retained within the two housing portions (not shown) of the housing 12. The circumferential lip 132 of the cylindrical hub 135 is located or "trapped" between the first and second housing portions 12a, 12b and is free to rotate in place within the groove. The circumferential bearing surface 140 bears against interior portions of the housing to assist proper rotation. Thus, the cylindrical hub 135 is free to rotate in place within the housing. The user engages the flutes 136 formed on the proximal rotation knob 134 with either the finger or the thumb to rotate the cylindrical hub 135 within the housing 12.

[0107] In one example embodiment, the cylindrical hub 135 may be formed of a durable plastic such as polycarbonate. In one example embodiment, the cylindrical hub 135 may be formed of a siliconized polycarbonate material. In one example embodiment, the proximal rotation knob 134 may be formed of pliable, resilient, flexible polymeric materials including Versaflex® TPE alloys made by GLS Corporation, for example. The proximal rotation knob 134 may be formed of elastomeric materials, thermoplastic rubber known as Santoprene®, other thermoplastic vulcanizates (TPVs), or elastomers, for example. The embodiments, however, are not limited in this context.

[0108] FIG. 10 illustrates one embodiment of a surgical system 200 including a surgical instrument 210 having single element end effector 278. The system 200 may include a transducer assembly 216 coupled to the end effector 278 and a sheath 256 positioned around the proximal portions of the end effector 278 as shown. The transducer assembly 216 and end effector 278 may operate in a manner similar to that of the transducer assembly 16 and end effector 18 described above to produce ultrasonic energy that may be transmitted to tissue via blade 226'.

[0109] FIGS. 11-18C illustrate various embodiments of surgical instruments that utilize therapeutic or sub-therapeutic electrical energy to treat and/or destroy tissue or provide feedback to the generators (e.g., electrosurgical instruments). The embodiments of FIGS. 11-18C are adapted for use in a manual or hand-operated manner although electrosurgical instruments may be utilized in robotic applications as well. FIG. 11 is a perspective view of one example embodiment of a surgical instrument system 300 comprising an electrical energy surgical instrument 310. The electrosurgical instrument 310 may comprise a proximal handle 312, a distal

working end or end effector 326 and an introducer or elongated shaft 314 disposed in-between.

[0110] The electrosurgical system 300 can be configured to supply energy, such as electrical energy, ultrasonic energy, heat energy, or any combination thereof, to the tissue of a patient either independently or simultaneously as described, for example, in connection with FIG. 1, for example. In one example embodiment, the electrosurgical system 300 includes a generator 320 in electrical communication with the electrosurgical instrument 310. The generator 320 is connected to electrosurgical instrument 310 via a suitable transmission medium such as a cable 322. In one example embodiment, the generator 320 is coupled to a controller, such as a control unit 325, for example. In various embodiments, the control unit 325 may be formed integrally with the generator 320 or may be provided as a separate circuit module or device electrically coupled to the generator 320 (shown in phantom to illustrate this option). Although in the presently disclosed embodiment, the generator 320 is shown separate from the electrosurgical instrument 310, in one example embodiment, the generator 320 (and/or the control unit 325) may be formed integrally with the electrosurgical instrument 310 to form a unitary electrosurgical system 300, where a battery located within the electrosurgical instrument 310 is the energy source and a circuit coupled to the battery produces the suitable electrical energy, ultrasonic energy, or heat energy. Once such example is described herein below, in connection with FIGS. 17-18C.

[0111] The generator 320 may comprise an input device 335 located on a front panel of the generator 320 console. The input device 335 may comprise any suitable device that generates signals suitable for programming the operation of the generator 320, such as a keyboard, or input port, for example. In one example embodiment, various electrodes in the first jaw 364A and the second jaw 364B may be coupled to the generator 320. The cable 322 may comprise multiple electrical conductors for the application of electrical energy to positive (+) and negative (-) electrodes of the electrosurgical instrument 310. The control unit 325 may be used to activate the generator 320, which may serve as an electrical source. In various embodiments, the generator 320 may comprise an RF source, an ultrasonic source, a direct current source, and/or any other suitable type of electrical energy source, for example, which may be activated independently or simultaneously.

[0112] In various embodiments, the electrosurgical system 300 may comprise at least one supply conductor 331 and at least one return conductor 333, wherein current can be supplied to electrosurgical instrument 300 via the supply conductor 331 and wherein the current can flow back to the generator 320 via the return conductor 333. In various embodiments, the supply conductor 331 and the return conductor 333 may comprise insulated wires and/or any other suitable type of conductor. In certain embodiments, as described below, the supply conductor 331 and the return conductor 333 may be contained within and/or may comprise the cable 322 extending between, or at least partially between, the generator 320 and the end effector 326 of the electrosurgical instrument 310. In any event, the generator 320 can be configured to apply a sufficient voltage differential between the supply conductor 331 and the return conductor 333 such that sufficient current can be supplied to the end effector 110.

[0113] FIG. 12 is a side view of one example embodiment of the handle 312 of the surgical instrument 310. In FIG. 12,

the handle 312 is shown with half of a first handle body 312A (see FIG. 11) removed to illustrate various components within second handle body 312B. The handle 312 may comprise a lever arm 321 (e.g., a trigger) which may be pulled along a path 33. The lever arm 321 may be coupled to an axially moveable member 378 (FIGS. 13-16) disposed within elongated shaft 314 by a shuttle 384 operably engaged to an extension 398 of lever arm 321. The shuttle 384 may further be connected to a biasing device, such as a spring 388, which may also be connected to the second handle body 312B, to bias the shuttle 384 and thus the axially moveable member 378 in a proximal direction, thereby urging the jaws 364A and 364B to an open position as seen in FIG. 11. Also, referring to FIGS. 11-12, a locking member 190 (see FIG. 12) may be moved by a locking switch 328 (see FIG. 11) between a locked position, where the shuttle 384 is substantially prevented from moving distally as illustrated, and an unlocked position, where the shuttle 384 may be allowed to freely move in the distal direction, toward the elongated shaft 314. The handle 312 can be any type of pistol-grip or other type of handle known in the art that is configured to carry actuator levers, triggers or sliders for actuating the first jaw 364A and the second jaw 364B. The elongated shaft 314 may have a cylindrical or rectangular cross-section, for example, and can comprise a thin-wall tubular sleeve that extends from handle 312. The elongated shaft 314 may include a bore extending therethrough for carrying actuator mechanisms, for example, the axially moveable member 378, for actuating the jaws and for carrying electrical leads for delivery of electrical energy to electrosurgical components of the end effector 326.

[0114] The end effector 326 may be adapted for capturing and transecting tissue and for the contemporaneously welding the captured tissue with controlled application of energy (e.g., RF energy). The first jaw 364A and the second jaw 364B may close to thereby capture or engage tissue about a longitudinal axis "T" defined by the axially moveable member 378. The first jaw 364A and second jaw 364B may also apply compression to the tissue. In some embodiments, the elongated shaft 314, along with first jaw 364A and second jaw 364B, can be rotated a full 360° degrees, as shown by arrow 196 (see FIG. 11), relative to handle 312. For example, a rotation knob 348 may be rotatable about the longitudinal axis of the elongated shaft 314 and may be coupled to the elongated shaft 314 such that rotation of the knob 348 causes corresponding rotation of the elongated shaft 314. The first jaw 364A and the second jaw 364B can remain openable and/or closeable while rotated.

[0115] FIG. 13 shows a perspective view of one example embodiment of the end effector 326 with the jaws 364A, 364B open, while FIG. 14 shows a perspective view of one example embodiment of the end effector 326 with the jaws 364A, 364B closed. As noted above, the end effector 326 may comprise the upper first jaw 364A and the lower second jaw 364B, which may be straight or curved. The first jaw 364A and the second jaw 364B may each comprise an elongated slot or channel 362A and 362B, respectively, disposed outwardly along their respective middle portions. Further, the first jaw 364A and second jaw 364B may each have tissue-gripping elements, such as teeth 363, disposed on the inner portions of first jaw 364A and second jaw 364B. The first jaw 364A may comprise an upper first jaw body 200A with an upper first outward-facing surface 202A and an upper first energy delivery surface 365A. The second jaw 364B may comprise a lower second jaw body 200B with a lower second

outward-facing surface 202B and a lower second energy delivery surface 365B. The first energy delivery surface 365A and the second energy delivery surface 365B may both extend in a “U” shape about the distal end of the end effector 326.

[0116] The lever arm 321 of the handle 312 (FIG. 12) may be adapted to actuate the axially moveable member 378, which may also function as a jaw-closing mechanism. For example, the axially moveable member 378 may be urged distally as the lever arm 321 is pulled proximally along the path 33 via the shuttle 384, as shown in FIG. 12 and discussed above. FIG. 15 is a perspective view of one example embodiment of the axially moveable member 378 of the surgical instrument 310. The axially moveable member 378 may comprise one or several pieces, but in any event, may be movable or translatable with respect to the elongated shaft 314 and/or the jaws 364A, 364B. Also, in at least one example embodiment, the axially moveable member 378 may be made of 17-4 precipitation hardened stainless steel. The distal end of axially moveable member 378 may comprise a flanged “I”-beam configured to slide within the channels 362A and 362B in jaws 364A and 364B. The axially moveable member 378 may slide within the channels 362A, 362B to open and close the first jaw 364A and the second jaw 364B. The distal end of the axially moveable member 378 may also comprise an upper flange or “c”-shaped portion 378A and a lower flange or “c”-shaped portion 378B. The flanges 378A and 378B respectively define inner cam surfaces 367A and 367B for engaging outward facing surfaces of the first jaw 364A and the second jaw 364B. The opening-closing of jaws 364A and 364B can apply very high compressive forces on tissue using cam mechanisms which may include movable “I-beam” axially moveable member 378 and the outward facing surfaces 369A, 369B of jaws 364A, 364B.

[0117] More specifically, referring now to FIGS. 13-15, collectively, the inner cam surfaces 367A and 367B of the distal end of axially moveable member 378 may be adapted to slidably engage the first outward-facing surface 369A and the second outward-facing surface 369B of the first jaw 364A and the second jaw 364B, respectively. The channel 362A within first jaw 364A and the channel 362B within the second jaw 364B may be sized and configured to accommodate the movement of the axially moveable member 378, which may comprise a tissue-cutting element 371, for example, comprising a sharp distal edge. FIG. 14, for example, shows the distal end of the axially moveable member 378 advanced at least partially through channels 362A and 362B (FIG. 13). The advancement of the axially moveable member 378 may close the end effector 326 from the open configuration shown in FIG. 13. In the closed position shown by FIG. 14, the upper first jaw 364A and lower second jaw 364B define a gap or dimension D between the first energy delivery surface 365A and second energy delivery surface 365B of first jaw 364A and second jaw 364B, respectively. In various embodiments, dimension D can equal from about 0.0005” to about 0.040”, for example, and in some embodiments, between about 0.001” to about 0.010”, for example. Also, the edges of the first energy delivery surface 365A and the second energy delivery surface 365B may be rounded to prevent the dissection of tissue.

[0118] FIG. 16 is a section view of one example embodiment of the end effector 326 of the surgical instrument 310. The engagement, or tissue-contacting, surface 365B of the lower jaw 364B is adapted to deliver energy to tissue, at least in part, through a conductive-resistive matrix, such as a vari-

able resistive positive temperature coefficient (PTC) body, as discussed in more detail below. At least one of the upper and lower jaws 364A, 364B may carry at least one electrode 373 configured to deliver the energy from the generator 320 to the captured tissue. The engagement, or tissue-contacting, surface 365A of upper jaw 364A may carry a similar conductive-resistive matrix (i.e., a PTC material), or in some embodiments the surface may be a conductive electrode or an insulative layer, for example. Alternatively, the engagement surfaces of the jaws can carry any of the energy delivery components disclosed in U.S. Pat. No. 6,773,409, filed Oct. 22, 2001, entitled ELECTROSURGICAL JAW STRUCTURE FOR CONTROLLED ENERGY DELIVERY, the entire disclosure of which is incorporated herein by reference.

[0119] The first energy delivery surface 365A and the second energy delivery surface 365B may each be in electrical communication with the generator 320. The first energy delivery surface 365A and the second energy delivery surface 365B may be configured to contact tissue and deliver electro-surgical energy to captured tissue which are adapted to seal or weld the tissue. The control unit 325 regulates the electrical energy delivered by electrical generator 320 which in turn delivers electrosurgical energy to the first energy delivery surface 365A and the second energy delivery surface 365B. The energy delivery may be initiated by an activation button 328 (FIG. 12) operably engaged with the lever arm 321 and in electrical communication with the generator 320 via cable 322. In one example embodiment, the electrosurgical instrument 310 may be energized by the generator 320 by way of a foot switch 329 (FIG. 11). When actuated, the foot switch 216 triggers the generator 320 to deliver electrical energy to the end effector 326, for example. The control unit 325 may regulate the power generated by the generator 320 during activation. Although the foot switch 329 may be suitable in many circumstances, other suitable types of switches can be used.

[0120] As mentioned above, the electrosurgical energy delivered by electrical generator 320 and regulated, or otherwise controlled, by the control unit 325 may comprise radio frequency (RF) energy, or other suitable forms of electrical energy. Further, the opposing first and second energy delivery surfaces 365A and 365B may carry variable resistive positive temperature coefficient (PTC) bodies that are in electrical communication with the generator 320 and the control unit 325. Additional details regarding electrosurgical end effectors, jaw closing mechanisms, and electrosurgical energy-delivery surfaces are described in the following U.S. patents and published patent applications: U.S. Pat. Nos. 7,087,054; 7,083,619; 7,070,597; 7,041,102; 7,011,657; 6,929,644; 6,926,716; 6,913,579; 6,905,497; 6,802,843; 6,770,072; 6,656,177; 6,533,784; and 6,500,312; and U.S. Pat. App. Pub. Nos. 2010/0036370 and 2009/0076506, all of which are incorporated herein in their entirety by reference and made a part of this specification.

[0121] In one example embodiment, the generator 320 may be implemented as an electrosurgery unit (ESU) capable of supplying power sufficient to perform bipolar electrosurgery using radio frequency (RF) energy. In one example embodiment, the ESU can be a bipolar ERBE ICC 350 sold by ERBE USA, Inc. of Marietta, Ga. In some embodiments, such as for bipolar electrosurgery applications, a surgical instrument having an active electrode and a return electrode can be utilized, wherein the active electrode and the return electrode can be positioned against, adjacent to and/or in electrical

communication with, the tissue to be treated such that current can flow from the active electrode, through the positive temperature coefficient (PTC) bodies and to the return electrode through the tissue. Thus, in various embodiments, the electrosurgical system 300 may comprise a supply path and a return path, wherein the captured tissue being treated completes, or closes, the circuit. In one example embodiment, the generator 320 may be a monopolar RF ESU and the electrosurgical instrument 310 may comprise a monopolar end effector 326 in which one or more active electrodes are integrated. For such a system, the generator 320 may require a return pad in intimate contact with the patient at a location remote from the operative site and/or other suitable return path. The return pad may be connected via a cable to the generator 320. In other embodiments, the operator 20 may provide sub-therapeutic RF energy levels for purposes of evaluating tissue conditions and providing feedback in the electrosurgical system 300. Such feedback may be employed to control the therapeutic RF energy output of the electrosurgical instrument 310.

[0122] During operation of electrosurgical instrument 300, the user generally grasps tissue, supplies energy to the captured tissue to form a weld or a seal (e.g., by actuating button 328 and/or pedal 216), and then drives a tissue-cutting element 371 at the distal end of the axially moveable member 378 through the captured tissue. According to various embodiments, the translation of the axial movement of the axially moveable member 378 may be paced, or otherwise controlled, to aid in driving the axially moveable member 378 at a suitable rate of travel. By controlling the rate of the travel, the likelihood that the captured tissue has been properly and functionally sealed prior to transection with the cutting element 371 is increased.

[0123] FIG. 17 is a perspective view of one example embodiment of a surgical instrument system comprising a cordless electrical energy surgical instrument 410. The electrosurgical system is similar to the electrosurgical system 300. The electrosurgical system can be configured to supply energy, such as electrical energy, ultrasonic energy, heat energy, or any combination thereof, to the tissue of a patient either independently or simultaneously as described in connection with FIGS. 1 and 11, for example. The electrosurgical instrument may utilize the end effector 326 and elongated shaft 314 described herein in conjunction with a cordless proximal handle 412. In one example embodiment, the handle 412 includes a generator circuit 420 (see FIG. 18A). The generator circuit 420 performs a function substantially similar to that of generator 320. In one example embodiment, the generator circuit 420 is coupled to a controller, such as a control circuit. In the illustrated embodiment, the control circuit is integrated into the generator circuit 420. In other embodiments, the control circuit may be separate from the generator circuit 420.

[0124] In one example embodiment, various electrodes in the end effector 326 (including jaws 364A, 364B thereof) may be coupled to the generator circuit 420. The control circuit may be used to activate the generator 420, which may serve as an electrical source. In various embodiments, the generator 420 may comprise an RF source, an ultrasonic source, a direct current source, and/or any other suitable type of electrical energy source, for example. In one example embodiment, a button 328 may be provided to activate the generator circuit 420 to provide energy to the end effectors 326, 326.

[0125] FIG. 18A is a side view of one example embodiment of the handle 412 of the cordless surgical instrument 410. In FIG. 18, the handle 412 is shown with half of a first handle body removed to illustrate various components within second handle body 434. The handle 412 may comprise a lever arm 424 (e.g., a trigger) which may be pulled along a path 33 around a pivot point. The lever arm 424 may be coupled to an axially moveable member 478 disposed within elongated shaft 314 by a shuttle operably engaged to an extension of lever arm 424. In one example embodiment, the lever arm 424 defines a shepherd's hook shape comprising a distal member 424a and a proximal member 424b.

[0126] In one example embodiment, the cordless electrosurgical instrument comprises a battery 437. The battery 437 provides electrical energy to the generator circuit 420. The battery 437 may be any battery suitable for driving the generator circuit 420 at the desired energy levels. In one example embodiment, the battery 437 is a 100 mAh, triple-cell Lithium Ion Polymer battery. The battery may be fully charged prior to use in a surgical procedure, and may hold a voltage of about 12.6V. The battery 437 may have two fuses fitted to the cordless electrosurgical instrument 410, arranged in line with each battery terminal. In one example embodiment, a charging port 439 is provided to connect the battery 437 to a DC current source (not shown).

[0127] The generator circuit 420 may be configured in any suitable manner. In some embodiments, the generator circuit comprises an RF drive and control circuit 440 and a controller circuit 482. FIG. 18B illustrates an RF drive and control circuit 440, according to one embodiment. FIG. 18B is a part schematic part block diagram illustrating the RF drive and control circuitry 440 used in this embodiment to generate and control the RF electrical energy supplied to the end effector 326. As will be explained in more detail below, in this embodiment, the drive circuitry 440 is a resonant mode RF amplifier comprising a parallel resonant network on the RF amplifier output and the control circuitry operates to control the operating frequency of the drive signal so that it is maintained at the resonant frequency of the drive circuit, which in turn controls the amount of power supplied to the end effector 326. The way that this is achieved will become apparent from the following description.

[0128] As shown in FIG. 18B, the RF drive and control circuit 440 comprises the above described battery 437 are arranged to supply, in this example, about 0V and about 12V rails. An input capacitor (C_{in}) 442 is connected between the 0V and the 12V for providing a low source impedance. A pair of FET switches 443-1 and 443-2 (both of which are N-channel in this embodiment to reduce power losses) is connected in series between the 0V rail and the 12V rail. FET gate drive circuitry 805 is provided that generates two drive signals—one for driving each of the two FETs 443. The FET gate drive circuitry 445 generates drive signals that causes the upper FET (443-1) to be on when the lower FET (443-2) is off and vice versa. This causes the node 447 to be alternately connected to the 12V rail (when the FET 443-1 is switched on) and the 0V rail (when the FET 443-2 is switched on). FIG. 18B also shows the internal parasitic diodes 448-1 and 448-2 of the corresponding FETs 443, which conduct during any periods that the FETs 443 are open.

[0129] As shown in FIG. 18B, the node 447 is connected to an inductor-inductor resonant circuit 450 formed by inductor L_s 452 and inductor L_m 454. The FET gate driving circuitry 445 is arranged to generate drive signals at a drive frequency

(f_d) that opens and crosses the FET switches **443** at the resonant frequency of the parallel resonant circuit **450**. As a result of the resonant characteristic of the resonant circuit **450**, the square wave voltage at node **447** will cause a substantially sinusoidal current at the drive frequency (f_d) to flow within the resonant circuit **450**. As illustrated in FIG. **18B**, the inductor L_m **454** is the primary of a transformer **455**, the secondary of which is formed by inductor L_{sec} **456**. The inductor L_{sec} **456** of the transformer **455** secondary is connected to an inductor-capacitor-capacitor parallel resonant circuit **457** formed by inductor L_2 **458**, capacitor C_4 **460**, and capacitor C_2 **462**. The transformer **455** up-converts the drive voltage (V_d) across the inductor L_m **454** to the voltage that is applied to the output parallel resonant circuit **457**. The load voltage (V_L) is output by the parallel resonant circuit **457** and is applied to the load (represented by the load resistance R_{load} **459** in FIG. **18B**) corresponding to the impedance of the forceps' jaws and any tissue or vessel gripped by the end effector **326**. As shown in FIG. **18B**, a pair of DC blocking capacitors C_{bl} **480-1** and **480-2** is provided to prevent any DC signal being applied to the load **459**.

[0130] In one embodiment, the transformer **455** may be implemented with a Core Diameter (mm), Wire Diameter (mm), and Gap between secondary windings in accordance with the following specifications:

[0131] Core Diameter, D (mm)

[0132] $D=19.9 \times 10^{-3}$

[0133] Wire diameter, W (mm) for 22 AWG wire

[0134] $W=7.366 \times 10^{-4}$

[0135] Gap between secondary windings, in gap=0.125

[0136] $G=\text{gap}/25.4$

[0137] In this embodiment, the amount of electrical power supplied to the end effector **326** is controlled by varying the frequency of the switching signals used to switch the FETs **443**. This works because the resonant circuit **450** acts as a frequency dependent (loss less) attenuator. The closer the drive signal is to the resonant frequency of the resonant circuit **450**, the less the drive signal is attenuated. Similarly, as the frequency of the drive signal is moved away from the resonant frequency of the circuit **450**, the more the drive signal is attenuated and so the power supplied to the load reduces. In this embodiment, the frequency of the switching signals generated by the FET gate drive circuitry **445** is controlled by a controller **481** based on a desired power to be delivered to the load **459** and measurements of the load voltage (V_L) and of the load current (I_L) obtained by conventional voltage sensing circuitry **483** and current sensing circuitry **485**. The way that the controller **481** operates will be described in more detail below.

[0138] In one embodiment, the voltage sensing circuitry **483** and the current sensing circuitry **485** may be implemented with high bandwidth, high speed rail-to-rail amplifiers (e.g., LMH6643 by National Semiconductor). Such amplifiers, however, consume a relatively high current when they are operational. Accordingly, a power save circuit may be provided to reduce the supply voltage of the amplifiers when they are not being used in the voltage sensing circuitry **483** and the current sensing circuitry **485**. In one-embodiment, a step-down regulator (e.g., LT3502 by Linear Technologies) may be employed by the power save circuit to reduce the supply voltage of the rail-to-rail amplifiers and thus extend the life of the battery **437**.

[0139] FIG. **18C** illustrates the main components of the controller **481**, according to one embodiment. In the embodi-

ment illustrated in FIG. **18C**, the controller **481** is a micro-processor based controller and so most of the components illustrated in FIG. **16** are software based components. Nevertheless, a hardware based controller **481** may be used instead. As shown, the controller **481** includes synchronous I,Q sampling circuitry **491** that receives the sensed voltage and current signals from the sensing circuitry **483** and **485** and obtains corresponding samples which are passed to a power, V_{rms} and I_{rms} calculation module **493**. The calculation module **493** uses the received samples to calculate the RMS voltage and RMS current applied to the load **459** (FIG. **18B**; end effector **326** and tissue/vessel gripped thereby) and from them the power that is presently being supplied to the load **459**. The determined values are then passed to a frequency control module **495** and a medical device control module **497**. The medical device control module **497** uses the values to determine the present impedance of the load **459** and based on this determined impedance and a pre-defined algorithm, determines what set point power (P_{set}) should be applied to the frequency control module **495**. The medical device control module **497** is in turn controlled by signals received from a user input module **499** that receives inputs from the user (for example pressing buttons or activating the control levers **114**, **110** on the handle **104**) and also controls output devices (lights, a display, speaker or the like) on the handle **104** via a user output module **461**.

[0140] The frequency control module **495** uses the values obtained from the calculation module **493** and the power set point (P_{set}) obtained from the medical device control module **497** and predefined system limits (to be explained below), to determine whether or not to increase or decrease the applied frequency. The result of this decision is then passed to a square wave generation module **463** which, in this embodiment, increments or decrements the frequency of a square wave signal that it generates by 1 kHz, depending on the received decision. As those skilled in the art will appreciate, in an alternative embodiment, the frequency control module **495** may determine not only whether to increase or decrease the frequency, but also the amount of frequency change required. In this case, the square wave generation module **463** would generate the corresponding square wave signal with the desired frequency shift. In this embodiment, the square wave signal generated by the square wave generation module **463** is output to the FET gate drive circuitry **445**, which amplifies the signal and then applies it to the FET **443-1**. The FET gate drive circuitry **445** also inverts the signal applied to the FET **443-1** and applies the inverted signal to the FET **443-2**.

[0141] The electrosurgical instrument **410** may comprise additional features as discussed with respect to electrosurgical system **300**. Those skilled in the art will recognize that electrosurgical instrument **410** may include a rotation knob **348**, an elongated shaft **314**, and an end effector **326**. These elements function in a substantially similar manner to that discussed above with respect to the electrosurgical system **300**. In one example embodiment, the cordless electrosurgical instrument **410** may include visual indicators **435**. The visual indicators **435** may provide a visual indication signal to an operator. In one example embodiment, the visual indication signal may alert an operator that the device is on, or that the device is applying energy to the end effector. Those skilled in the art will recognize that the visual indicators **435** may be configured to provide information on multiple states of the device.

[0142] Over the years a variety of minimally invasive robotic (or “telesurgical”) systems have been developed to increase surgical dexterity as well as to permit a surgeon to operate on a patient in an intuitive manner. Robotic surgical systems can be used with many different types of surgical instruments including, for example, ultrasonic or electrosurgical instruments, as described herein. Example robotic systems include those manufactured by Intuitive Surgical, Inc., of Sunnyvale, Calif., U.S.A. Such systems, as well as robotic systems from other manufacturers, are disclosed in the following U.S. Patents which are each herein incorporated by reference in their respective entirety: U.S. Pat. No. 5,792,135, entitled “Articulated Surgical Instrument For Performing Minimally Invasive Surgery With Enhanced Dexterity and Sensitivity”, U.S. Pat. No. 6,231,565, entitled “Robotic Arm DLUS For Performing Surgical Tasks”, U.S. Pat. No. 6,783,524, entitled “Robotic Surgical Tool With Ultrasound Cauterizing and Cutting Instrument”, U.S. Pat. No. 6,364,888, entitled “Alignment of Master and Slave In a Minimally Invasive Surgical Apparatus”, U.S. Pat. No. 7,524,320, entitled “Mechanical Actuator Interface System For Robotic Surgical Tools”, U.S. Pat. No. 7,691,098, entitled Platform Link Wrist Mechanism”, U.S. Pat. No. 7,806,891, entitled “Repositioning and Reorientation of Master/Slave Relationship in Minimally Invasive Telesurgery”, and U.S. Pat. No. 7,824,401, entitled “Surgical Tool With Writed Monopolar Electrosurgical End Effectors”. Many of such systems, however, have in the past been unable to generate the magnitude of forces required to effectively cut and fasten tissue.

[0143] FIGS. 19-46C illustrate example embodiments of robotic surgical systems. In some embodiments, the disclosed robotic surgical systems may utilize the ultrasonic or electrosurgical instruments described herein. Those skilled in the art will appreciate that the illustrated robotic surgical systems are not limited to only those instruments described herein, and may utilize any compatible surgical instruments. Those skilled in the art will further appreciate that while various embodiments described herein may be used with the described robotic surgical systems, the disclosure is not so limited, and may be used with any compatible robotic surgical system.

[0144] FIGS. 19-25 illustrate the structure and operation of several example robotic surgical systems and components thereof. FIG. 19 shows a block diagram of an example robotic surgical system 1000. The system 1000 comprises at least one controller 508 and at least one arm cart 510. The arm cart 510 may be mechanically coupled to one or more robotic manipulators or arms, indicated by box 512. Each of the robotic arms 512 may comprise one or more surgical instruments 514 for performing various surgical tasks on a patient 504. Operation of the arm cart 510, including the arms 512 and instruments 514 may be directed by a clinician 502 from a controller 508. In some embodiments, a second controller 508', operated by a second clinician 502' may also direct operation of the arm cart 510 in conjunction with the first clinician 502. For example, each of the clinicians 502, 502' may control different arms 512 of the cart or, in some cases, complete control of the arm cart 510 may be passed between the clinicians 502, 502'. In some embodiments, additional arm carts (not shown) may be utilized on the patient 504. These additional arm carts may be controlled by one or more of the controllers 508, 508'. The arm cart(s) 510 and controllers 508, 508' may be in communication with one another via a communications link 516, which may be any suitable type of wired or wireless

communications link carrying any suitable type of signal (e.g., electrical, optical, infrared, etc.) according to any suitable communications protocol. Example implementations of robotic surgical systems, such as the system 1000, are disclosed in U.S. Pat. No. 7,524,320 which has been herein incorporated by reference. Thus, various details of such devices will not be described in detail herein beyond that which may be necessary to understand various embodiments of the claimed device.

[0145] FIG. 20 shows one example embodiment of a robotic arm cart 520. The robotic arm cart 520 is configured to actuate a plurality of surgical instruments or instruments, generally designated as 522 within a work envelope 519. Various robotic surgery systems and methods employing master controller and robotic arm cart arrangements are disclosed in U.S. Pat. No. 6,132,368, entitled “Multi-Component Telepresence System and Method”, the full disclosure of which is incorporated herein by reference. In various forms, the robotic arm cart 520 includes a base 524 from which, in the illustrated embodiment, three surgical instruments 522 are supported. In various forms, the surgical instruments 522 are each supported by a series of manually articulatable linkages, generally referred to as set-up joints 526, and a robotic manipulator 528. These structures are herein illustrated with protective covers extending over much of the robotic linkage. These protective covers may be optional, and may be limited in size or entirely eliminated in some embodiments to minimize the inertia that is encountered by the servo mechanisms used to manipulate such devices, to limit the volume of moving components so as to avoid collisions, and to limit the overall weight of the cart 520. Cart 520 will generally have dimensions suitable for transporting the cart 520 between operating rooms. The cart 520 may be configured to typically fit through standard operating room doors and onto standard hospital elevators. In various forms, the cart 520 would preferably have a weight and include a wheel (or other transportation) system that allows the cart 520 to be positioned adjacent an operating table by a single attendant.

[0146] FIG. 21 shows one example embodiment of the robotic manipulator 528 of the robotic arm cart 520. In the example shown in FIG. 21, the robotic manipulators 528 may include a linkage 530 that constrains movement of the surgical instrument 522. In various embodiments, linkage 530 includes rigid links coupled together by rotational joints in a parallelogram arrangement so that the surgical instrument 522 rotates around a point in space 532, as more fully described in issued U.S. Pat. No. 5,817,084, the full disclosure of which is herein incorporated by reference. The parallelogram arrangement constrains rotation to pivoting about an axis 534a, sometimes called the pitch axis. The links supporting the parallelogram linkage are pivotally mounted to set-up joints 526 (FIG. 20) so that the surgical instrument 522 further rotates about an axis 534b, sometimes called the yaw axis. The pitch and yaw axes 534a, 534b intersect at the remote center 536, which is aligned along a shaft 538 of the surgical instrument 522. The surgical instrument 522 may have further degrees of driven freedom as supported by manipulator 540, including sliding motion of the surgical instrument 522 along the longitudinal instrument axis “LT-LT”. As the surgical instrument 522 slides along the instrument axis LT-LT relative to manipulator 540 (arrow 534c), remote center 536 remains fixed relative to base 542 of manipulator 540. Hence, the entire manipulator 540 is generally moved to re-position remote center 536. Linkage 530

of manipulator **540** is driven by a series of motors **544**. These motors **544** actively move linkage **530** in response to commands from a processor of a control system. As will be discussed in further detail below, motors **544** are also employed to manipulate the surgical instrument **522**.

[0147] FIG. 22 shows one example embodiment of a robotic arm cart **520'** having an alternative set-up joint structure. In this example embodiment, a surgical instrument **522** is supported by an alternative manipulator structure **528'** between two tissue manipulation instruments. Those of ordinary skill in the art will appreciate that various embodiments of the claimed device may incorporate a wide variety of alternative robotic structures, including those described in U.S. Pat. No. 5,878,193, the full disclosure of which is incorporated herein by reference. Additionally, while the data communication between a robotic component and the processor of the robotic surgical system is primarily described herein with reference to communication between the surgical instrument **522** and the controller, it should be understood that similar communication may take place between circuitry of a manipulator, a set-up joint, an endoscope or other image capture device, or the like, and the processor of the robotic surgical system for component compatibility verification, component-type identification, component calibration (such as off-set or the like) communication, confirmation of coupling of the component to the robotic surgical system, or the like.

[0148] FIG. 23 shows one example embodiment of a controller **518** that may be used in conjunction with a robotic arm cart, such as the robotic arm carts **520**, **520'** depicted in FIGS. 20-22. The controller **518** generally includes master controllers (generally represented as **519** in FIG. 23) which are grasped by the clinician and manipulated in space while the clinician views the procedure via a stereo display **521**. A surgeon feed back meter **515** may be viewed via the display **521** and provide the surgeon with a visual indication of the amount of force being applied to the cutting instrument or dynamic clamping member. The master controllers **519** generally comprise manual input devices which preferably move with multiple degrees of freedom, and which often further have a handle or trigger for actuating instruments (for example, for closing grasping saws, applying an electrical potential to an electrode, or the like).

[0149] FIG. 24 shows one example embodiment of an ultrasonic surgical instrument **522** adapted for use with a robotic surgical system. For example, the surgical instrument **522** may be coupled to one of the surgical manipulators **528**, **528'** described hereinabove. As can be seen in FIG. 24, the surgical instrument **522** comprises a surgical end effector **548** that comprises an ultrasonic blade **550** and clamp arm **552**, which may be coupled to an elongated shaft assembly **554** that, in some embodiments, may comprise an articulation joint **556**. FIG. 25 shows another example embodiment having an electrosurgical instrument **523** in place of the ultrasonic surgical instrument **522**. The surgical instrument **523** comprises a surgical end effector **548** that comprises closable jaws **551A**, **551B** having energy deliver surfaces **553A**, **553B** for engaging and providing electrical energy to tissue between the jaws **551A**, **551B**. A tissue cutting element or knife **555** may be positioned at the distal end of an axially movable member **557** that may extend through the elongated shaft assembly **554** to the instrument mounting portion **558**. FIG. 26 shows one example embodiment of an instrument drive assembly **546** that may be coupled to one of the surgical manipulators **528**,

528' to receive and control the surgical instruments **522**, **523**. The instrument drive assembly **546** may also be operatively coupled to the controller **518** to receive inputs from the clinician for controlling the instrument **522**, **523**. For example, actuation (i.e., opening and closing) of the clamp arm **552**, actuation (i.e., opening and closing) of the jaws **551A**, **551B**, actuation of the ultrasonic blade **550**, extension of the knife **555** and actuation of the energy delivery surfaces **553A**, **553B**, etc. may be controlled through the instrument drive assembly **546** based on inputs from the clinician provided through the controller **518**. The surgical instrument **522** is operably coupled to the manipulator by an instrument mounting portion, generally designated as **558**. The surgical instruments **522** further include an interface **560** which mechanically and electrically couples the instrument mounting portion **558** to the manipulator.

[0150] FIG. 27 shows another view of the instrument drive assembly of FIG. 26 including the ultrasonic surgical instrument **522**. FIG. 28 shows another view of the instrument drive assembly of FIG. 26 including the electrosurgical instrument **523**. The instrument mounting portion **558** includes an instrument mounting plate **562** that operably supports a plurality of (four are shown in FIG. 26) rotatable body portions, driven discs or elements **564**, that each include a pair of pins **566** that extend from a surface of the driven element **564**. One pin **566** is closer to an axis of rotation of each driven elements **564** than the other pin **566** on the same driven element **564**, which helps to ensure positive angular alignment of the driven element **564**. The driven elements **564** and pins **566** may be positioned on an adapter side **567** of the instrument mounting plate **562**.

[0151] Interface **560** also includes an adaptor portion **568** that is configured to mountingly engage the mounting plate **562** as will be further discussed below. The adaptor portion **568** may include an array of electrical connecting pins **570**, which may be coupled to a memory structure by a circuit board within the instrument mounting portion **558**. While interface **560** is described herein with reference to mechanical, electrical, and magnetic coupling elements, it should be understood that a wide variety of telemetry modalities might be used, including infrared, inductive coupling, or the like.

[0152] FIGS. 29-31 show additional views of the adaptor portion **568** of the instrument drive assembly **546** of FIG. 26. The adaptor portion **568** generally includes an instrument side **572** and a holder side **574** (FIG. 29). In various embodiments, a plurality of rotatable bodies **576** are mounted to a floating plate **578** which has a limited range of movement relative to the surrounding adaptor structure normal to the major surfaces of the adaptor **568**. Axial movement of the floating plate **578** helps decouple the rotatable bodies **576** from the instrument mounting portion **558** when the levers **580** along the sides of the instrument mounting portion housing **582** are actuated (See FIGS. 24, 25) Other mechanisms/arrangements may be employed for releasably coupling the instrument mounting portion **558** to the adaptor **568**. In at least one form, rotatable bodies **576** are resiliently mounted to floating plate **578** by resilient radial members which extend into a circumferential indentation about the rotatable bodies **576**. The rotatable bodies **576** can move axially relative to plate **578** by deflection of these resilient structures. When disposed in a first axial position (toward instrument side **572**) the rotatable bodies **576** are free to rotate without angular limitation. However, as the rotatable bodies **576** move axially toward instrument side **572**, tabs **584** (extending radially from the rotatable

bodies 576) laterally engage detents on the floating plates so as to limit angular rotation of the rotatable bodies 576 about their axes. This limited rotation can be used to help drivingly engage the rotatable bodies 576 with drive pins 586 of a corresponding instrument holder portion 588 of the robotic system, as the drive pins 586 will push the rotatable bodies 576 into the limited rotation position until the pins 586 are aligned with (and slide into) openings 590.

[0153] Openings 590 on the instrument side 572 and openings 590 on the holder side 574 of rotatable bodies 576 are configured to accurately align the driven elements 564 (FIGS. 27, 28) of the instrument mounting portion 558 with the drive elements 592 of the instrument holder 588. As described above regarding inner and outer pins 566 of driven elements 564, the openings 590 are at differing distances from the axis of rotation on their respective rotatable bodies 576 so as to ensure that the alignment is not 33 degrees from its intended position. Additionally, each of the openings 590 may be slightly radially elongated so as to fittingly receive the pins 566 in the circumferential orientation. This allows the pins 566 to slide radially within the openings 590 and accommodate some axial misalignment between the instrument 522, 523 and instrument holder 588, while minimizing any angular misalignment and backlash between the drive and driven elements. Openings 590 on the instrument side 572 may be offset by about 90 degrees from the openings 590 (shown in broken lines) on the holder side 574, as can be seen most clearly in FIG. 31.

[0154] Various embodiments may further include an array of electrical connector pins 570 located on holder side 574 of adaptor 568, and the instrument side 572 of the adaptor 568 may include slots 594 (FIG. 31) for receiving a pin array (not shown) from the instrument mounting portion 558. In addition to transmitting electrical signals between the surgical instrument 522, 523 and the instrument holder 588, at least some of these electrical connections may be coupled to an adaptor memory device 596 (FIG. 30) by a circuit board of the adaptor 568.

[0155] A detachable latch arrangement 598 may be employed to releasably affix the adaptor 568 to the instrument holder 588. As used herein, the term “instrument drive assembly” when used in the context of the robotic system, at least encompasses various embodiments of the adapter 568 and instrument holder 588 and which has been generally designated as 546 in FIG. 26. For example, as can be seen in FIG. 26, the instrument holder 588 may include a first latch pin arrangement 600 that is sized to be received in corresponding clevis slots 602 provided in the adaptor 568. In addition, the instrument holder 588 may further have second latch pins 604 that are sized to be retained in corresponding latch clevises 606 in the adaptor 568. See FIG. 30. In at least one form, a latch assembly 608 is movably supported on the adapter 568 and is biasable between a first latched position wherein the latch pins 600 are retained within their respective latch clevis 606 and an unlatched position wherein the second latch pins 604 may be into or removed from the latch clevises 606. A spring or springs (not shown) are employed to bias the latch assembly into the latched position. A lip on the instrument side 572 of adaptor 568 may slidably receive laterally extending tabs of instrument mounting housing 582.

[0156] As described the driven elements 564 may be aligned with the drive elements 592 of the instrument holder 588 such that rotational motion of the drive elements 592 causes corresponding rotational motion of the driven ele-

ments 564. The rotation of the drive elements 592 and driven elements 564 may be electronically controlled, for example, via the robotic arm 612, in response to instructions received from the clinician 502 via a controller 508. The instrument mounting portion 558 may translate rotation of the driven elements 564 into motion of the surgical instrument 522, 523.

[0157] FIGS. 32-34 show one example embodiment of the instrument mounting portion 558 showing components for translating motion of the driven elements 564 into motion of the surgical instrument 522, 523. FIGS. 32-34 show the instrument mounting portion with a shaft 538 having a surgical end effector 610 at a distal end thereof. The end effector 610 may be any suitable type of end effector for performing a surgical task on a patient. For example, the end effector may be configured to provide RF and/or ultrasonic energy to tissue at a surgical site. The shaft 538 may be rotatably coupled to the instrument mounting portion 558 and secured by a top shaft holder 646 and a bottom shaft holder 648 at a coupler 650 of the shaft 538.

[0158] In one example embodiment, the instrument mounting portion 558 comprises a mechanism for translating rotation of the various driven elements 564 into rotation of the shaft 538, differential translation of members along the axis of the shaft (e.g., for articulation), and reciprocating translation of one or more members along the axis of the shaft 538 (e.g., for extending and retracting tissue cutting elements such as 555, overtubes and/or other components). In one example embodiment, the rotatable bodies 612 (e.g., rotatable spools) are coupled to the driven elements 564. The rotatable bodies 612 may be formed integrally with the driven elements 564. In some embodiments, the rotatable bodies 612 may be formed separately from the driven elements 564 provided that the rotatable bodies 612 and the driven elements 564 are fixedly coupled such that driving the driven elements 564 causes rotation of the rotatable bodies 612. Each of the rotatable bodies 612 is coupled to a gear train or gear mechanism to provide shaft articulation and rotation and clamp jaw open/close and knife actuation.

[0159] In one example embodiment, the instrument mounting portion 558 comprises a mechanism for causing differential translation of two or more members along the axis of the shaft 538. In the example provided in FIGS. 32-34, this motion is used to manipulate articulation joint 556. In the illustrated embodiment, for example, the instrument mounting portion 558 comprises a rack and pinion gearing mechanism to provide the differential translation and thus the shaft articulation functionality. In one example embodiment, the rack and pinion gearing mechanism comprises a first pinion gear 614 coupled to a rotatable body 612 such that rotation of the corresponding driven element 564 causes the first pinion gear 614 to rotate. A bearing 616 is coupled to the rotatable body 612 and is provided between the driven element 564 and the first pinion gear 614. The first pinion gear 614 is meshed to a first rack gear 618 to convert the rotational motion of the first pinion gear 614 into linear motion of the first rack gear 618 to control the articulation of the articulation section 556 of the shaft assembly 538 in a left direction 620L. The first rack gear 618 is attached to a first articulation band 622 (FIG. 32) such that linear motion of the first rack gear 618 in a distal direction causes the articulation section 556 of the shaft assembly 538 to articulate in the left direction 620L. A second pinion gear 626 is coupled to another rotatable body 612 such that rotation of the corresponding driven element 564 causes the second pinion gear 626 to rotate. A bearing 616 is coupled

to the rotatable body 612 and is provided between the driven element 564 and the second pinion gear 626. The second pinion gear 626 is meshed to a second rack gear 628 to convert the rotational motion of the second pinion gear 626 into linear motion of the second rack gear 628 to control the articulation of the articulation section 556 in a right direction 620R. The second rack gear 628 is attached to a second articulation band 624 (FIG. 33) such that linear motion of the second rack gear 628 in a distal direction causes the articulation section 556 of the shaft assembly 538 to articulate in the right direction 620R. Additional bearings may be provided between the rotatable bodies and the corresponding gears. Any suitable bearings may be provided to support and stabilize the mounting and reduce rotary friction of shaft and gears, for example.

[0160] In one example embodiment, the instrument mounting portion 558 further comprises a mechanism for translating rotation of the driven elements 564 into rotational motion about the axis of the shaft 538. For example, the rotational motion may be rotation of the shaft 538 itself. In the illustrated embodiment, a first spiral worm gear 630 coupled to a rotatable body 612 and a second spiral worm gear 632 coupled to the shaft assembly 538. A bearing 616 (FIG. 17) is coupled to a rotatable body 612 and is provided between a driven element 564 and the first spiral worm gear 630. The first spiral worm gear 630 is meshed to the second spiral worm gear 632, which may be coupled to the shaft assembly 538 and/or to another component of the instrument 522, 523 for which longitudinal rotation is desired. Rotation may be caused in a clockwise (CW) and counter-clockwise (CCW) direction based on the rotational direction of the first and second spiral worm gears 630, 632. Accordingly, rotation of the first spiral worm gear 630 about a first axis is converted to rotation of the second spiral worm gear 632 about a second axis, which is orthogonal to the first axis. As shown in FIGS. 32-33, for example, a CW rotation of the second spiral worm gear 632 results in a CW rotation of the shaft assembly 538 in the direction indicated by 634CW. A CCW rotation of the second spiral worm gear 632 results in a CCW rotation of the shaft assembly 538 in the direction indicated by 634CCW. Additional bearings may be provided between the rotatable bodies and the corresponding gears. Any suitable bearings may be provided to support and stabilize the mounting and reduce rotary friction of shaft and gears, for example.

[0161] In one example embodiment, the instrument mounting portion 558 comprises a mechanism for generating reciprocating translation of one or more members along the axis of the shaft 538. Such translation may be used, for example to drive a tissue cutting element, such as 555, drive an overtube for closure and/or articulation of the end effector 610, etc. In the illustrated embodiment, for example, a rack and pinion gearing mechanism may provide the reciprocating translation. A first gear 636 is coupled to a rotatable body 612 such that rotation of the corresponding driven element 564 causes the first gear 636 to rotate in a first direction. A second gear 638 is free to rotate about a post 640 formed in the instrument mounting plate 562. The first gear 636 is meshed to the second gear 638 such that the second gear 638 rotates in a direction that is opposite of the first gear 636. In one example embodiment, the second gear 638 is a pinion gear meshed to a rack gear 642, which moves in a linear direction. The rack gear 642 is coupled to a translating block 644, which may translate distally and proximally with the rack gear 642. The translation block 644 may be coupled to any suitable component of the shaft assembly 538 and/or the end effector 610 so as to

provide reciprocating longitudinal motion. For example, the translation block 644 may be mechanically coupled to the tissue cutting element 555 of the RF surgical device 523. In some embodiments, the translation block 644 may be coupled to an overtube, or other component of the end effector 610 or shaft 538.

[0162] FIGS. 35-37 illustrate an alternate embodiment of the instrument mounting portion 558 showing an alternate example mechanism for translating rotation of the driven elements 564 into rotational motion about the axis of the shaft 538 and an alternate example mechanism for generating reciprocating translation of one or more members along the axis of the shaft 538. Referring now to the alternate rotational mechanism, a first spiral worm gear 652 is coupled to a second spiral worm gear 654, which is coupled to a third spiral worm gear 656. Such an arrangement may be provided for various reasons including maintaining compatibility with existing robotic systems 500 and/or where space may be limited. The first spiral worm gear 652 is coupled to a rotatable body 612. The third spiral worm gear 656 is meshed with a fourth spiral worm gear 658 coupled to the shaft assembly 538. A bearing 760 is coupled to a rotatable body 612 and is provided between a driven element 564 and the first spiral worm gear 738. Another bearing 760 is coupled to a rotatable body 612 and is provided between a driven element 564 and the third spiral worm gear 652. The third spiral worm gear 652 is meshed to the fourth spiral worm gear 658, which may be coupled to the shaft assembly 538 and/or to another component of the instrument 522, 523 for which longitudinal rotation is desired. Rotation may be caused in a CW and a CCW direction based on the rotational direction of the spiral worm gears 656, 658. Accordingly, rotation of the third spiral worm gear 656 about a first axis is converted to rotation of the fourth spiral worm gear 658 about a second axis, which is orthogonal to the first axis. As shown in FIGS. 0 and P, for example, the fourth spiral worm gear 558 is coupled to the shaft 538, and a CW rotation of the fourth spiral worm gear 658 results in a CW rotation of the shaft assembly 538 in the direction indicated by 634CW. A CCW rotation of the fourth spiral worm gear 658 results in a CCW rotation of the shaft assembly 538 in the direction indicated by 634CCW. Additional bearings may be provided between the rotatable bodies and the corresponding gears. Any suitable bearings may be provided to support and stabilize the mounting and reduce rotary friction of shaft and gears, for example.

[0163] Referring now to the alternate example mechanism for generating reciprocating translation of one or more members along the axis of the shaft 538, the instrument mounting portion 558 comprises a rack and pinion gearing mechanism to provide reciprocating translation along the axis of the shaft 538 (e.g., translation of a tissue cutting element 555 of the RF surgical device 523). In one example embodiment, a third pinion gear 660 is coupled to a rotatable body 612 such that rotation of the corresponding driven element 564 causes the third pinion gear 660 to rotate in a first direction. The third pinion gear 660 is meshed to a rack gear 662, which moves in a linear direction. The rack gear 662 is coupled to a translating block 664. The translating block 664 may be coupled to a component of the device 522, 523, such as, for example, the tissue cutting element 555 of the RF surgical device and/or an overtube or other component which is desired to be translated longitudinally.

[0164] FIGS. 38-42 illustrate an alternate embodiment of the instrument mounting portion 558 showing another alter-

nate example mechanism for translating rotation of the driven elements 564 into rotational motion about the axis of the shaft 538. In FIGS. 38-42, the shaft 538 is coupled to the remainder of the mounting portion 558 via a coupler 676 and a bushing 678. A first gear 666 coupled to a rotatable body 612, a fixed post 668 comprising first and second openings 672, first and second rotatable pins 674 coupled to the shaft assembly, and a cable 670 (or rope). The cable is wrapped around the rotatable body 612. One end of the cable 670 is located through a top opening 672 of the fixed post 668 and fixedly coupled to a top rotatable pin 674. Another end of the cable 670 is located through a bottom opening 672 of the fixed post 668 and fixedly coupled to a bottom rotating pin 674. Such an arrangement is provided for various reasons including maintaining compatibility with existing robotic systems 500 and/or where space may be limited. Accordingly, rotation of the rotatable body 612 causes the rotation about the shaft assembly 538 in a CW and a CCW direction based on the rotational direction of the rotatable body 612 (e.g., rotation of the shaft 538 itself). Accordingly, rotation of the rotatable body 612 about a first axis is converted to rotation of the shaft assembly 538 about a second axis, which is orthogonal to the first axis. As shown in FIGS. 38, 39, for example, a CW rotation of the rotatable body 612 results in a CW rotation of the shaft assembly 538 in the direction indicated by 634CW. A CCW rotation of the rotatable body 612 results in a CCW rotation of the shaft assembly 538 in the direction indicated by 634CCW. Additional bearings may be provided between the rotatable bodies and the corresponding gears. Any suitable bearings may be provided to support and stabilize the mounting and reduce rotary friction of shaft and gears, for example.

[0165] FIGS. 43-46A illustrate an alternate embodiment of the instrument mounting portion 558 showing an alternate example mechanism for differential translation of members along the axis of the shaft 538 (e.g., for articulation). For example, as illustrated in FIGS. 43-46A, the instrument mounting portion 558 comprises a double cam mechanism 680 to provide the shaft articulation functionality. In one example embodiment, the double cam mechanism 680 comprises first and second cam portions 680A, 680B. First and second follower arms 682, 684 are pivotally coupled to corresponding pivot spools 686. As the rotatable body 612 coupled to the double cam mechanism 680 rotates, the first cam portion 680A acts on the first follower arm 682 and the second cam portion 680B acts on the second follower arm 684. As the cam mechanism 680 rotates the follower arms 682, 684 pivot about the pivot spools 686. The first follower arm 682 may be attached to a first member that is to be differentially translated (e.g., the first articulation band 622). The second follower arm 684 is attached to a second member that is to be differentially translated (e.g., the second articulation band 624). As the top cam portion 680A acts of the first follower arm 682, the first and second members are differentially translated. In the example embodiment where the first and second members are the respective articulation bands 622 and 624, the shaft assembly 538 articulates in a left direction 620L. As the bottom cam portion 680B acts of the second follower arm 684, the shaft assembly 538 articulates in a right direction 620R. In some example embodiments, two separate bushings 688, 690 are mounted beneath the respective first and second follower arms 682, 684 to allow the rotation of the shaft without affecting the articulating positions of the first and second follower arms 682, 684. For articulation motion, these bushings reciprocate with the first and second follower

arms 682, 684 without affecting the rotary position of the jaw 902. FIG. 46 shows the bushings 688, 690 and the dual cam assembly 680, including the first and second cam portions 680B, 680B, with the first and second follower arms 682, 684 removed to provide a more detailed and clearer view.

[0166] In various embodiments, the instrument mounting portion 558 may additionally comprise internal energy sources for driving electronics and provided desired ultrasonic and/or RF frequency signals to surgical tools. FIGS. 46B-46C illustrate one embodiment of a tool mounting portion 558' comprising internal power and energy sources. For example, surgical instruments (e.g., instruments 522, 523) mounted utilizing the tool mounting portion 558' need not be wired to an external generator or other power source. Instead, the functionality of the various generators 20, 320 described herein may be implemented on board the mounting portion 558.

[0167] As illustrated in FIGS. 46B-46C, the instrument mounting portion 558' may comprise a distal portion 702. The distal portion 702 may comprise various mechanisms for coupling rotation of drive elements 612 to end effectors of the various surgical instruments 522, 523, for example, as described herein above. Proximal of the distal portion 702, the instrument mounting portion 558' comprises an internal direct current (DC) energy source and an internal drive and control circuit 704. In the illustrated embodiment, the energy source comprises a first and second battery 706, 708. In other respects, the tool mounting portion 558' is similar to the various embodiments of the tool mounting portion 558 described herein above.

[0168] The control circuit 704 may operate in a manner similar to that described above with respect to generators 20, 320. For example, when an ultrasonic instrument 522 is utilized, the control circuit 704 may provide an ultrasonic drive signal in a manner similar to that described above with respect to generator 20. Also, for example, when an RF instrument 523 or ultrasonic instrument 522 capable of providing a therapeutic or non-therapeutic RF signal is used, the control circuit 704 may provide an RF drive signal, for example, as described herein above with respect to the module 23 of generator 20 and/or the generator 300. In some embodiments, the control circuit 704 may be configured in a manner similar to that of the control circuit 440 described herein above with respect to FIGS. 18B-18C.

[0169] In some embodiments, it may be desirable to prevent actuation of an electrosurgical or ultrasonic end effector, such as, for example, the electrosurgical end effector 523, until energy has been applied to the electrosurgical or ultrasonic end effector. FIG. 47 shows one embodiment of an instrument mounting portion 758 comprising a lockout mechanism 722. In the embodiment shown in FIG. 47, actuation of the one or more members of end effector 723, such as, for example, a blade, may be prohibited through the use of a lockout mechanism 722. The lockout mechanism 722 operably interfaces with one or more of the mechanisms for generating reciprocating translation of one or more members along the axis of the shaft 738. In the embodiment shown in FIG. 47, the lockout mechanism interfaces directly with the shaft 738 to prevent reciprocal movement of the one or more members along the axis of the shaft 738. In other embodiments, the lockout mechanism 722 may interface with the one or more of the gears, such as, for example, the first gear 636 of the instrument mounting portion 758.

[0170] As shown in FIG. 47, the lockout mechanism may be directly connected to a switch 714, such as, for example, a foot switch. The switch 714 may be operated by a user to selectively disengage (or selectively engage) the lockout mechanism 722 to prevent reciprocating movement of the end effector 723. In the illustrated embodiment, the switch 714 is directly connected to the lockout mechanism 722 by a wire 716. It will be appreciated by those skilled in the art that the switch 714 and the lockout mechanism 722 may be in signal communication by a suitable method, including, but not limited to, direct communication, communication through one or more controllers, such as, for example, the robotic surgical control systems disclosed in co-filed application END7042USNP/110388. In other embodiments, the lockout mechanism 722 and the switch 714 may be in wireless communication using any suitable wireless communication protocol, such as, for example, Bluetooth communication.

[0171] The switch 714 may also be connected to the generator 712. The generator 712 is configured to provide one or more electrosurgical signals to the end effector 723. The electrosurgical signals delivered by the generator 712 may include, but are not limited to, ultrasonic signals, radiofrequency signals, or a combination thereof. A user may cause the generator to deliver the electrosurgical signal to the end effector 723 by activating the switch 714. In the illustrated embodiment, the lockout mechanism 722 and the generator 712 are controlled by the switch 714 such that reciprocating movement of the end effector 723 is allowed only when electrosurgical energy is being delivered to the end effector 723.

[0172] In another embodiment, the lockout mechanism 722 may be directly coupled to the generator 712 or the end effector 723. In this embodiment, the lockout mechanism 722 may be controlled by sensing the presence of the electrosurgical signal delivered by the generator 712 to the end effector 723. In this embodiment, the lockout mechanism 722 may prevent actuation of the one or more members of the end effector 723 if the generator 712 is faulty or is has not delivered the proper amount of energy to the end effector 723.

[0173] The instrument mounting portion 758 comprises an end-of-stroke switch 718 operatively coupled to the reciprocating movement element 724. The end-of-stroke switch 718 provides a signal indicative of the location of the one or more members within the end effector 723. In one embodiment, the end-of-stroke switch 718 may provide a feedback signal to a user indicating that the one or members have reached the distal most point of the reciprocating travel path. The user may then activate a reverse stroke algorithm to cause the one or more members to return from the distal most position to a proximal most, or starting, position. In another embodiment, the end-of-stroke switch 718 may cause the reverse stroke algorithm to automatically activate. In one embodiment, the end-of-stroke switch 718 may be connected to the lockout mechanism 722 such that the end-of-stroke switch 718 may engage the lockout mechanism 722 to prevent the one or more members of the end effector 723 from extending beyond a maximum distal displacement. In one embodiment, the end-of-stroke switch may prevent a signal from the switch 714 from being transmitted to the lockout mechanism 722 when the end-of-stroke switch 718 is activated, causing the lockout mechanism 722 to assume the default, locked position.

[0174] FIG. 48 illustrates one embodiment of instrument mounting portion 558 including a lockout mechanism 802. The lockout mechanism 802 mechanically interfaces with the

first gear 636, which is coupled to a rotatable body 612. The lockout mechanism 802 prevents rotation of the first gear 636 by providing a mechanical stoppage interfaced with the first gear 636 from rotating. The mechanical stoppage may be, for example, a solenoid, a third gear, or any other suitable lockout device.

[0175] In one embodiment, the lockout mechanism is electrically coupled to a control switch located on the controller 518 (not shown). The control switch may be configured to control the delivery of energy to the end effector 610 from a generator, such as, for example, generator 320 (see FIG. 11). By actuating the control switch, a user may cause electrical energy to be delivered to the end effector 610 sufficient for use in electrosurgical applications.

[0176] In one embodiment, the control switch, in addition to allowing delivery of electrical energy to the end effector 610, causes the lockout mechanism 802 to disengage from the first gear 636, allowing rotation of the first gear 636 by the rotatable body 612. In this embodiment, the lockout mechanism 802 is directly connected to the delivery of electrical energy to the end effector 610. In other embodiments, the lockout mechanism 802 may be controlled by a second switch which is not used for delivery of electrical energy to the end effector 610.

[0177] In one embodiment, the end effector 723 may have a first state and a second state. In one embodiment, the first state may comprise a default, de-energized state wherein no energy is being applied by the generator 712 to the end effector 723. The second state may correspond to an energized state wherein the end effector 723 is energized by one or more forms of energy delivered by the generator 712. In one embodiment, in the energized state, the end effector may be energized with ultrasonic energy, radiofrequency energy, or both forms of energy. The lockout mechanism 722 may be electrically coupled to the end effector 723 such that the lockout mechanism 722 prevents actuation of the one or more members of the end effector 723 when the end effector 723 is in the first state and allows actuation of the one or more members when the end effector 723 is in the second state. In another embodiment, the first and second states may correspond to one or more mechanical states of the end effector 723, such as, for example, an end effector 723 comprising a staple cartridge may have a first state in which the staple cartridge is unloaded and a second state in which the staple cartridge is loaded. Those skilled in the art will appreciate that the first and second states may correspond to any suitable functions of the end effector 723.

[0178] As shown in FIG. 48, in one embodiment the lockout mechanism may comprise a solenoid 820. The solenoid 820 may be a linear pull type solenoid. In a pull type solenoid the plunger, such as, for example, armature 822, is biased in an extended position by a spring located within the solenoid. When the solenoid is energized, a coil (in the case of an electromagnetic solenoid) or a cylinder (in the case of a pneumatic solenoid) causes the plunger to retract into the body of the solenoid. The plunger returns to its biased, extended state when the solenoid is no longer energized. The solenoid 820 is a pull type solenoid with a default position of an extended armature 822, causing the default position of the lockout mechanism 802 to engage the first gear 636. Therefore, the default position of the lockout mechanism 802 is in a locked position. The solenoid 820 may also be a push type

solenoid, wherein the biased and unbiased positions are reversed, and therefore would have a default position of an unlocked position.

[0179] In one embodiment, the instrument mounting portion **558** further comprises an end-of-stroke switch **818**. The end-of-stroke switch **818** is operatively coupled to the mechanism for generating reciprocating translation of one or more members along the axis of the shaft **538**. In the embodiment shown in FIG. **48**, the end-of-stroke switch **818** is operatively coupled to the second gear **638**. The end-of-stroke switch **818** provides a signal indicating that the one or more members have reached the distal most point of its reciprocating travel path within channel of the end effector **610**.

[0180] In one embodiment, the end-of-stroke switch **818** may provide a feedback signal to a user indicating that the one or more members have reached the distal most point of the reciprocating travel path. The user may then activate a reverse stroke algorithm to cause the one or more members to return from the distal most position to a proximal most, or starting, position. In another embodiment, the end-of-stroke switch **818** may cause the reverse stroke algorithm to automatically activate. In this embodiment, the end-of-stroke switch **818** may be connected to a processor or other controller to reverse the direction of rotation of the rotatable body **612**. In this embodiment, a user may activate a switch on a controller, such as controller **518**, causing energy to be applied to the end effector **610**. After energy has been applied, the controller may then actuate the solenoid **820** allowing the first gear **636** to rotate in response to rotation of the rotatable body **612** in a first direction. The rotation of the rotatable body **612** in the first direction causes one or more members, such as tissue cutting element **555**, to advance in a distal direction with respect to the instrument mounting portion housing **582**. Once the tissue cutting element **555** has reached the distal-most point of travel, the end-of-stroke switch **818** activates, causing the controller to reverse the direction of rotation of the rotatable body and the tissue cutting element **555** to travel in a proximal direction relative to the instrument mounting portion housing **582**. Once the tissue cutting element **555** has returned to the proximal most position, the end-of-stroke switch **818** is again activated by the second gear **638**, which causes the rotatable body **612** to cease rotating and re-engages the lockout mechanism **802** with the first gear **636**.

[0181] FIG. **49** illustrates one embodiment of the lockout mechanism **902** directly interfaced with the fourth spiral worm gear **658** of the shaft assembly **538**. In this embodiment, the lockout mechanism **902** prevents the fourth spiral worm gear **658** from being rotated by the third spiral worm gear **656**. In this embodiment, the lockout mechanism **902** prevents reciprocating movement of the one or more members by preventing rotation of the fourth worm gear **656** which is coupled to the shaft assembly **538**.

[0182] In one embodiment, the lockout mechanism **722**, **802**, **902** may be controlled by one or more logic controls (not shown). The one or more logic controls may be located, for example, in the instrument mounting portion assembly **558** or on the controller **518**. The one or more logic controls may control the lockout mechanism **722** to allow reciprocating movement of the one or more members during specific sequences controlled by the one or more logic controls, such as, for example, a cutting and sealing algorithm controlled by one or more processors included with the controller **518**. The one or more logic controls may be any suitable logic for controlling the lockout mechanism **722**, such as, for example,

a computer processor running one or more software programs thereon or a programmable logic circuit, such as a field programmable gate array.

[0183] In one embodiment, the end-of-stroke switch **718** may be coupled to the one or more logic controls to provide a control signal for one or more functions controlled by the one or more logic controls. For example, in one embodiment, the end-of-stroke switch **718** may provide a signal to the one or more logic controls which cause the one or more logic controls to reverse the direction of travel of the one or more members of the end effector **723**. In this embodiment, the one or more logic controls may automatically retract the one or more members to a proximal, or starting, position after the end-of-stroke switch **718** indicates that the one or more members have reached the distal-most position.

NON-LIMITING EXAMPLES

[0184] In one embodiment a surgical system is provided. The surgical system comprises a surgical tool, comprising an instrument mounting portion comprising a housing; a plate; a shaft assembly comprising an end effector, the end effector comprising a first jaw member and a second jaw member, the first and second jaw members defining a channel therebetween, and a blade slideably receivable within the channel to cut tissue located between the first and second jaw members; and a coupler to couple the shaft assembly to the instrument mounting portion; an actuation mechanism to actuate the end effector, wherein the actuation mechanism provides reciprocating movement of the blade within the channel; a lockout mechanism coupled to the actuation mechanism, the lockout mechanism to selectively enable reciprocating movement of the blade; and an interface to mechanically and electrically couple the instrument mounting portion to a manipulator; and a triggering mechanism for selectively activating the lockout mechanism.

[0185] In one embodiment a surgical tool is provided. The surgical tool comprises an instrument mounting portion housing; an instrument mounting portion plate; and a coupler to couple a shaft assembly to the instrument mounting portion, the shaft assembly comprising a RF end effector, the RF end effector having a first state wherein the RF end effector is energized with RF energy and a second state wherein the RF end effector is not energized with RF energy; an end effector actuation mechanism configured to actuate the RF end effector; a lockout mechanism coupled to the end effector actuation mechanism, wherein the wherein the lockout mechanism is mechanically coupled to the end effector actuation mechanism to allow actuation of the end effector actuation mechanism when the RF end effector is in the first state and to prevent actuation of the end effector actuation mechanism when the RF end effector is in the second state, wherein the lockout mechanism is a solenoid; and an interface to mechanically and electrically couple the instrument mounting portion to a manipulator.

[0186] Applicant also owns the following patent applications that are each incorporated by reference in their respective entireties:

[0187] U.S. patent application Ser. No. 13/536,271, filed on Jun. 28, 2012 and entitled "Flexible Drive Member," (Attorney Docket No. END7131USNP/120135);

[0188] U.S. patent application Ser. No. 13/536,288, filed on Jun. 28, 2012 and entitled "Multi-Functional Powered Surgical Device with External Dissection Features," (Attorney Docket No. END7132USNP/120136);

[0194] U.S. patent application Ser. No. 13/536,417, filed on Jun. 28, 2012 and entitled “Electrode Connections for Rotary Driven Surgical Tools,” (Attorney Docket No. END7149USNP/120153).

[0195] It will be appreciated that the terms “proximal” and “distal” are used throughout the specification with reference to a clinician manipulating one end of an instrument used to treat a patient. The term “proximal” refers to the portion of the instrument closest to the clinician and the term “distal” refers to the portion located furthest from the clinician. It will further be appreciated that for conciseness and clarity, spatial terms such as “vertical,” “horizontal,” “up,” or “down” may be used herein with respect to the illustrated embodiments. However, surgical instruments may be used in many orientations and positions, and these terms are not intended to be limiting or absolute.

[0196] Various embodiments of surgical instruments and robotic surgical systems are described herein. It will be understood by those skilled in the art that the various embodiments described herein may be used with the described surgical instruments and robotic surgical systems. The descriptions are provided for example only, and those skilled in the art will understand that the disclosed embodiments are not limited to only the devices disclosed herein, but may be used with any compatible surgical instrument or robotic surgical system.

[0197] Reference throughout the specification to “various embodiments,” “some embodiments,” “one example embodiment,” or “an embodiment” means that a particular feature, structure, or characteristic described in connection with the embodiment is included in at least one example embodiment. Thus, appearances of the phrases “in various embodiments,” “in some embodiments,” “in one example embodiment,” or “in an embodiment” in places throughout the specification are not necessarily all referring to the same embodiment. Furthermore, the particular features, structures, or characteristics illustrated or described in connection with one example embodiment may be combined, in whole or in part, with features, structures, or characteristics of one or more other embodiments without limitation.

[0198] While various embodiments herein have been illustrated by description of several embodiments and while the illustrative embodiments have been described in considerable detail, it is not the intention of the applicant to restrict or in any way limit the scope of the appended claims to such detail.

Additional advantages and modifications may readily appear to those skilled in the art. For example, it is generally accepted that endoscopic procedures are more common than laparoscopic procedures. Accordingly, the present invention has been discussed in terms of endoscopic procedures and apparatus. However, use herein of terms such as “endoscopic”, should not be construed to limit the present invention to an instrument for use only in conjunction with an endoscopic tube (e.g., trocar). On the contrary, it is believed that the present invention may find use in any procedure where access is limited to a small incision, including but not limited to laparoscopic procedures, as well as open procedures.

[0199] It is to be understood that at least some of the figures and descriptions herein have been simplified to illustrate elements that are relevant for a clear understanding of the disclosure, while eliminating, for purposes of clarity, other elements. Those of ordinary skill in the art will recognize, however, that these and other elements may be desirable. However, because such elements are well known in the art, and because they do not facilitate a better understanding of the disclosure, a discussion of such elements is not provided herein.

[0200] While several embodiments have been described, it should be apparent, however, that various modifications, alterations and adaptations to those embodiments may occur to persons skilled in the art with the attainment of some or all of the advantages of the disclosure. For example, according to various embodiments, a single component may be replaced by multiple components, and multiple components may be replaced by a single component, to perform a given function or functions. This application is therefore intended to cover all such modifications, alterations and adaptations without departing from the scope and spirit of the disclosure as defined by the appended claims.

[0201] Any patent, publication, or other disclosure material, in whole or in part, that is said to be incorporated by reference herein is incorporated herein only to the extent that the incorporated materials does not conflict with existing definitions, statements, or other disclosure material set forth in this disclosure. As such, and to the extent necessary, the disclosure as explicitly set forth herein supersedes any conflicting material incorporated herein by reference. Any material, or portion thereof, that is said to be incorporated by reference herein, but which conflicts with existing definitions, statements, or other disclosure material set forth herein will only be incorporated to the extent that no conflict arises between that incorporated material and the existing disclosure material.

What is claimed is:

1. A surgical tool, comprising:

an instrument mounting portion comprising:

a housing;

a plate;

a shaft assembly comprising an end effector, the end effector comprising a first jaw member and a second jaw member, the first and second jaw members defining a channel therebetween, and a blade slideably receivable within the channel to cut tissue located between the first and second jaw members; and

a coupler to couple the shaft assembly to the instrument mounting portion;

an actuation mechanism to actuate the end effector, wherein the actuation mechanism provides reciprocating movement of the blade within the channel;

a lockout mechanism coupled to the actuation mechanism, the lockout mechanism to selectively enable reciprocating movement of the blade; and
 an interface to mechanically and electrically couple the instrument mounting portion to a manipulator.

2. The surgical tool of claim 1, wherein:
 the end effector has a first state and a second state, wherein the lockout mechanism is configured to enable operation of the end effector actuation mechanism when the end effector is in the first state and to disable operation of the end effector actuation mechanism when the end effector is in the second state.

3. The surgical tool of claim 2, wherein the first state comprises an energized state and the second state comprises a de-energized state.

4. The surgical tool of claim 3, wherein the energized state comprises energizing the end effector with electrosurgical energy.

5. The surgical tool of claim 3, wherein the energized state comprises energizing the end effector with ultrasonic energy.

6. The surgical tool of claim 3, wherein the energized state comprises energizing the end effector with electrosurgical energy and ultrasonic energy.

7. The surgical tool of claim 1, wherein the lockout mechanism comprises a mechanical actuator arranged to engage the actuation mechanism when in a deployed state, wherein the mechanical actuator prevents movement of the actuation mechanism while in the deployed state.

8. The surgical tool of claim 7, wherein the mechanical actuator is a solenoid.

9. The surgical tool of claim 1, comprising an end of stroke indicator coupled to the end effector actuation mechanism such that the end of stroke indicator prevents the end effector actuation mechanism from extending beyond a predetermined maximum deployment.

10. A surgical system, comprising:
 a surgical tool, comprising:
 an instrument mounting portion comprising:
 a housing;
 a plate;
 a shaft assembly comprising an end effector, the end effector comprising a first jaw member and a second jaw member, the first and second jaw members defining a channel therebetween, and a blade slidably receivable within the channel to cut tissue located between the first and second jaw members;
 and
 a coupler to couple the shaft assembly to the instrument mounting portion;
 an actuation mechanism to actuate the end effector, wherein the actuation mechanism provides reciprocating movement of the blade within the channel;
 a lockout mechanism coupled to the actuation mechanism, the lockout mechanism to selectively enable reciprocating movement of the blade; and
 an interface to mechanically and electrically couple the instrument mounting portion to a manipulator; and

a triggering mechanism for selectively activating the lockout mechanism.

11. The surgical system of claim 10, wherein the controller controls a state of the RF end effector, wherein the RF end effector has a first state wherein the RF end effector is energized by an energy source and a second state wherein the RF end effector is not energized by an energy source, and wherein the controller may selectively place the RF end effector in the first and second states.

12. The surgical system of claim 11,

wherein the lockout mechanism is configured to allow actuation of the end effector actuation mechanism when the RF end effector is in the first state; and

wherein the lockout mechanism is configured to prevent actuation of the end effector actuation mechanism when the RF end effector is in the second state.

13. The surgical system of claim 11, wherein the controller is a foot pedal.

14. The surgical tool of claim 10, comprising an end of stroke indicator.

15. The surgical tool of claim 14, wherein the end of stroke indicator activates a return-path action for the knife.

16. The surgical tool of claim 10, wherein the end effector actuation mechanism comprises a rack and pinion.

17. The surgical tool of claim 10, wherein the end effector actuation mechanism comprises one or more worm gears.

18. The surgical tool of claim 10, wherein the lockout mechanism comprises a mechanical actuator arranged to engage end effector actuation mechanism when in a deployed state.

19. The surgical tool of claim 18, wherein the mechanical actuator is a solenoid.

20. A surgical tool comprising:

an instrument mounting portion housing;

an instrument mounting portion plate; and

a coupler to couple a shaft assembly to the instrument mounting portion, the shaft assembly comprising a RF end effector, the RF end effector having a first state wherein the RF end effector is energized with RF energy and a second state wherein the RF end effector is not energized with RF energy;

an end effector actuation mechanism configured to actuate the RF end effector;

a lockout mechanism coupled to the end effector actuation mechanism, wherein the wherein the lockout mechanism is mechanically coupled to the end effector actuation mechanism to allow actuation of the end effector actuation mechanism when the RF end effector is in the first state and to prevent actuation of the end effector actuation mechanism when the RF end effector is in the second state, wherein the lockout mechanism is a solenoid; and

an interface to mechanically and electrically couple the instrument mounting portion to a manipulator.

摘要(译)

提供一种包括锁定机构的机器人控制的手术工具。手术工具可包括器械安装部分。器械安装部分包括壳体, 板, 包括末端执行器的轴组件, 以及将轴组件连接到器械安装部分的耦合器。末端执行器包括第一钳口构件和第二钳口构件, 第一钳口构件和第二钳口构件之间限定通道, 并且刀片可滑动地容纳在通道内以切割位于第一和第二钳口构件之间的组织。手术工具可包括致动机构, 以致动末端执行器以提供刀片在通道内的往复运动。锁定机构联接到致动机构。锁定机构可选择性地实现叶片的往复运动。接口将仪器安装部分机械地和电气地耦合到机器人操纵器。
