(54) Title: IMMUNOASSAY WITH ENHANCED SENSITIVITY

# Direct Assay Elution

(57) Abstract: The present invention is directed to methods for increasing sensitivities of immunoassays. The invention utilizes an acid elution condition that preferentially elute specifically bound immune complexes over non-specifically bound complexes from a solid phase, and designs immunoassay protocols that improve the ratio of specific binding to non-specific binding and thereby improving assay sensitivity. The protocol determines the signal of the labeled immunocomplexes eluted from a solid phase.

## IMMUNOASSAY WITH ENHANCED SENSITIVITY

### BACKGROUND OF THE INVENTION

Improving immunoassay sensitivity has been a longstanding goal in development of  
5 in vitro diagnostic tests. The benefits of sensitive biomarker measurements for early disease  
detection and cost effectiveness in patient triage are well documented. Over time many  
clinical assays have been offered in several generations where each subsequent iteration  
features improved sensitivity. Troponin I immunoassays are one such example where high  
sensitivity versions represent the state of the art.

10 Several clinical factors are responsible for driving the adoption of highly sensitive  
troponin I (hsTnI) assays. There is recognition that normal patients have circulating, low  
levels of TnI in the range of single digit pg/ml. Secondly, small heart attacks have TnI  
levels very similar to normal. Consequently, the ability to detect TnI within the normal range  
is critical. Apple (Clin. Chem., 55: 1303-1306, 2009) reports the designation of hsTnI assays  
15 centering on performance with normal samples. Figure 1 shows the parameters that hsTnI  
assays must meet. Greater than 50% of normal must be detected and imprecision at the 99<sup>th</sup>  
percentile of the normal distribution must be <10% to be guideline acceptable or 10 – 20% to  
be clinically useful.

Figure 2 illustrates a typical sandwich immunoassay format with a capture antibody  
20 and a labeled antibody, where the capture antibody is immobilized on a solid phase. There  
are two basic types of binding by the labeled antibody. Immuno-specific binding occurs  
when the labeled antibody forms a complex with antigen on the solid phase. This is the  
relevant specific binding since it enables antigen detection. The second type of binding is  
non-specific where the labeled antibody binds to the solid phase by means other than the  
25 specific antigen. Every solid phase configured sandwich immunoassay has some  
combination of specific versus non-specific binding. With high sensitivity immunoassays the  
ratio of specific to non-specific binding becomes crucial at low antigens levels.  
Consequently, developers of high sensitivity assays strive to maximize specific binding while  
seeking means to minimize non-specific binding.

### BRIEF DESCRIPTION OF THE DRAWINGS

30 FIG.1 shows the parameters that highly sensitive troponin I (hsTnI) must meet based  
on normal.

FIG. 2 illustrates a typical solid phase sandwich immunoassay format. AB= antibody, AG= antigen.

FIG. 3 illustrate one embodiment of the fluorescent detection system, which detects the fluorescence on the probe tip.

5 FIG. 4 illustrates an alternative fluorescent detection system. The optics with a wide laser beam and numerical aperture of the collecting lens detect the eluted labeled antibody in a liquid phase.

FIG. 5 illustrates a method of detecting an analyte in a liquid sample, using fluorescence-labeled antibody and acid elution protocols in a direct antibody binding assay.  
10 The fluorescent signal of eluted materials is calculated by subtracting a second fluorescent signal read on a probe from a first fluorescent signal read on the probe. Ab: antibody.

FIG. 6 illustrates a method of detecting an analyte in a liquid sample, using a binding pair and a high molecular weight polymer having multiple fluorescent labels in an amplification assay. Ag: antigen; AB: antibody; B-AB: biotin-Antibody; Cy5-SA: Cy5-  
15 Streptavidin.

FIG. 7 illustrates a method of detecting an analyte in a liquid sample in a cyclic amplification assay. FIG. 7 is similar to FIG. 6, except FIG. 7 has additional cyclic amplification steps to improve sensitivity.

## 20 DETAILED DESCRIPTION OF THE INVENTION

### Definitions

Terms used in the claims and specification are to be construed in accordance with their usual meaning as understood by one skilled in the art except and as defined as set forth below.

25 "About," as used herein, refers to within  $\pm 10\%$  of the recited value.

An "analyte-binding" molecule, as used herein, refers to any molecule capable of participating in a specific binding reaction with an analyte molecule. Examples include but are not limited to, (i) antigen molecules, for use in detecting the presence of antibodies specific against that antigen; (ii) antibody molecules, for use in detecting the presence of  
30 antigens; (iii) protein molecules, for use in detecting the presence of a binding partner for that protein; (iv) ligands, for use in detecting the presence of a binding partner; or (v) single stranded nucleic acid molecules, for detecting the presence of nucleic acid binding molecules.

An “aspect ratio” of a shape refers to the ratio of its longer dimension to its shorter dimension.

A “binding molecular,” refers to a molecule that is capable to bind another molecule of interest.

5 “A binding pair,” as used herein, refers to two molecules that are attracted to each other and specifically bind to each other. Examples of binding pairs include, but not limited to, an antigen and an antibody against the antigen, a ligand and its receptor, complementary strands of nucleic acids, biotin and avidin, biotin and streptavidin, biotin and neutravidin (a deglycosylated version of avidin), lectin and carbohydrates. Preferred binding pairs are  
10 biotin and streptavidin, biotin and avidin, biotin and neutravidin, fluorescein and anti-fluorescein, digioxygenin/anti-digioxygenin, and DNP (dinitrophenol) and anti-DNP.

A “branched polymer,” as used herein, refers to a non-linear polymer having a 2- or 3-dimensional structure, which can be either a naturally occurring branched polymer, or a synthetically crosslinked polymer.

15 “Chemiluminescence,” as used herein, refers to the emission of energy with limited emission of luminescence, as the result of a chemical reaction. For example, when luminol reacts with hydrogen peroxide in the presence of a suitable catalyst, it produces 3-aminophthalate in an excited state, which emits light when it decays to a lower energy level.

“Electrochemiluminescence,” (ECL), as used herein, refers to luminescence produced  
20 during electrochemical reactions in solutions. In ECL, electrochemically generated intermediates undergo a highly exergonic reaction to produce an electronically excited state and then emits light. ECL excitation is caused by energetic electron transfer (redox) reactions of electrogenerated species. ECL is usually observed during application of potential (several volts) to electrodes of electrochemical cell that contains solution of luminescent  
25 species.

“Immobilized,” as used herein, refers to reagents being fixed to a solid surface. When a reagent is immobilized to a solid surface, it is either be non-covalently bound or covalently bound to the surface.

30 “A monolithic substrate,” as used herein, refers to a single piece of a solid material such as glass, quartz, or plastic that has one refractive index.

A “probe,” as used herein, refers to a solid phase substrate coated with a thin-film layer of analyte-binding molecules at the sensing side. A probe has a distal end and a

proximal end. The proximal end (also refers to probe tip in the application) has a sensing surface coated with a thin layer of analyte-binding molecules.

5 The present invention relates to a method to increase signal to background ratio in an immunoassay and thus increasing the assay sensitivity. The inventors have discovered that conditions to elute specific immune complexes from a solid phase are different from conditions to elute non-specific complexes. The inventors have discovered elution conditions that preferentially elute specific immune complexes over non-specific complexes from a solid phase, and then designed immunoassay protocols that improve the measured ratio of specific  
10 binding to non-specific binding and thereby improving assay sensitivity. This invention detects an analyte by determining the signals of the labeled immunocomplex eluted from a solid phase, after it is bound on a solid phase.

#### **Fluorescent Detection System**

15 The present invention may use any suitable luminescent detection system. In one embodiment, the present invention uses a fluorescent detection system similar to that described in U.S. Patent No. 8,492,139, which is incorporated herein by reference in its entirety, for measuring a fluorescent signal on a probe tip. The system comprises: (a) a probe having an aspect ratio of length to width at least 5 to 1, the probe having a first end and a  
20 second end, the second end having a sensing surface bound with a fluorescent label; (b) a light source for emitting excitation light directly to the probe's sensing surface; (c) a collecting lens pointed toward the sensing surface; and (d) an optical detector for detecting the emission fluorescent light; where the collecting lens collects and directs the emission fluorescent light to the optical detector.

25 The probe can be a monolithic substrate or an optical fiber. The probe can be any shape such as rod, cylindrical, round, square, triangle, etc., with an aspect ratio of length to width of at least 5 to 1, preferably 10 to 1. Because the probe is dipped in a sample solution and one or more assay solutions during an immunoassay, it is desirable to have a long probe with an aspect ratio of at least 5 to 1 to enable the probe tip's immersion into the solutions.  
30 The sensing surface of the probe is coated with analyte-binding molecules and bound with fluorescent labels.

Any light source that can emit proper excitation light for the fluorescent label is suitable for the present invention. A prefer light source is a laser that can emit light with

wavelengths suitable for fluorescent labels. For example, the laser center wavelength is preferred to be 649 nm for Cy5 fluorescent dye. A suitable optical detector for detecting emission light is a photomultiplier tube (PMT), a charge coupled device (CCD), or a photodiode.

5           The light source and the optical detector including the collecting lens are mounted on the same side of the probe tip surface (the sensing surface). If the sensing surface faces down, they are both mounted below the tip surface. If the sensing surface faces up, they are both mounted above the tip surface. They are closer to the sensing surface than the other end of the probe. The sensing surface is always within the numeric aperture of the collecting lens.  
10   The probe can be, but does not have to be centrally aligned with the collecting lens.

FIG. 3 illustrate one embodiment of the fluorescent detection system which measures the fluorescent signals on the probe tip.

FIG. 4 illustrates an alternative optical detection configuration. The optics with a wide laser beam and numerical aperture of the collecting lens detect the eluted labeled  
15   antibody in fluid phase. This design has several advantages. Measurement of fluorescence at the probe tip demands selection of probe material with low background fluorescence. In this alternative configuration, the fluorescence is in the liquid phase. Since the probe is no longer in the measurement step, it provides a greater selection of solid phase material for the probe. Further, the wide beam laser and broad field of fluorescence collection require less critical  
20   alignment of the optics, which leads to lower cost and more robust instrumentation.

### **Direct Antibody Binding Assay**

In a first aspect, the present invention is directed to a method of detecting an analyte in a liquid sample, using luminescent-labeled antibody and acid elution protocols.

25           In one embodiment, the luminescent signal of eluted materials is calculated by subtracting a second luminescent signal on a probe from a first luminescent signal on the probe. The method comprises the steps of: (a) dipping a probe tip into a sample vessel containing a sample solution to bind an analyte, if present, to the first antibody on the probe tip, wherein the probe having a first antibody against the analyte immobilized on the tip of  
30   the probe; (b) dipping the probe tip into a reagent vessel containing a reagent solution comprising a second antibody against the analyte, conjugated with luminescent labels to form an immunocomplex among the analyte, the first antibody, and the second antibody on the probe tip; (c) dipping the probe tip into a washing vessel containing a wash solution; (d)

dipping the probe tip in a read vessel and measuring a first luminescent signal of materials bound on the probe tip; (e) dipping the probe tip into an elution solution having pH 2.0-5.0 to elute materials from the probe tip; (f) dipping the probe tip in the read vessel and measuring a second luminescent signal of materials bound on the probe tip; (g) calculating the  
5 luminescent signal of eluted materials by subtracting the second luminescent signal from the first luminescent signal, and determining the analyte amount. The method is illustrated in FIG. 5.

In the present method, the probe is immobilized with an antibody against the analyte, before the assay. Methods to immobilize a first antibody to a solid phase (the sensing surface  
10 of the probe tip) are common in immunochemistry and involve formation of covalent, hydrophobic or electrostatic bonds between the solid phase and antibody. The first antibody, also called capture antibody for its ability to capture the analyte, can be directly immobilized on the sensing surface by various methods known in the art. For example, a first antibody can be directly immobilized either by adsorption to the solid surface or by covalently binding  
15 to aminopropylsilane coated on the solid surface. Alternatively, the first antibody can be indirectly immobilized on the sensing surface through a binding pair. For example, the first antibody can be labeled with biotin by known techniques (see Wilchek and Bayer, (1988) Anal. Biochem. 171:1-32), and then be indirectly immobilized on the sensing surface coated with streptavidin. Biotin and streptavidin are a preferred binding pair due to their strong  
20 binding affinity, which does not dissociate during the regeneration steps of the present method. The capture antibody immobilized on the sensing surface must be able to survive the denaturation condition when the probe sensing surface is regenerated to remove the immunocomplex bound to the sensing surface after the immunoreaction. The capture antibody immobilized on the sensing surface must not lose a significant amount of activity or  
25 significantly disassociate from the solid phase so that the immunoassay performance is compromised.

In one embodiment, the present method uses a probe that has a small tip for binding an analyte. The tip has a smaller surface area with a diameter  $\leq 5$  mm, preferably  $\leq 2$  mm or  $\leq 1$  mm. The small surface of the probe tip endows it with several advantages. In a solid  
30 phase immunoassays, having a small surface area is advantageous because it has less non-specific binding and thus produces a lower background signal. Further, the reagent or sample carry over on the probe tip is extremely small due to the small surface area of the tip. This

feature makes the probe tip easy to wash, and causes negligible contamination in the wash solution since the wash solution has a larger volume.

In step (a) of the method, the probe tip is dipped into a sample vessel (or a sample chamber or a sample well), and incubated for a period of time, to bind the analyte to the first antibody on the probe tip. The incubation time preferably is a short period of time ( $\leq 5$  or 10 minutes), for example, is 5 seconds to 5 minutes, 10 seconds to 2 minutes, 30 seconds to 2 minutes, 10 seconds to 1 minute, or 30 seconds to 1 minute.

After step (a), the probe is optionally washed 1-5 times, preferably 1-3 times in a wash vessel (or a wash chamber or a wash well) containing an aqueous wash solution. This washing step may not be required if the carried-over solution is minimal. The wash solution typically contains buffer and a surfactant such as Tween 20.

In step (b) of the method, the probe tip is dipped into a reagent vessel (or a reagent chamber or a reagent well) to bind the reagent to the analyte on the probe tip. The incubation time preferably is a short period of time ( $\leq 5$  or 10 minutes), for example, is 5 seconds to 5 minutes, 10 seconds to 2 minutes, 30 seconds to 2 minutes, 10 seconds to 1 minute, or 30 seconds to 1 minute. The reagent solution comprises a luminescent labelled second antibody (a signal antibody).

Any suitable luminescent label such as fluorescent label or chemiluminescent can be used in this method. The fluorescent label useful for this invention has a molecular weight of  $< 5,000$ , preferably  $< 2,000$ , such as 500-2000 or 100-2000 Daltons. In one embodiment, the fluorescent dye is selected from the group consisting of: cyanine, coumarin, xanthene and a derivative thereof. For example, the fluorescent dye is Cy5 (molecule weight MW 792), Alexa Fluor 647, DyLight 350 (MW 874), DyLight 405 (MW 793), DyLight 488 (MW 71011), DyLight 550 (MW 982), DyLight 594 (MW 1078), DyLight 633 (MW 1066), DyLight 650 (MW 1008), DyLight 680 (MW 950), DyLight 755 (MW 1092), DyLight 800 (MW 1050), an Oyster fluorescent dye, IRDye, or organic compounds comprising multiple rings chelated with a rare earth metal such as a lanthanide (Eu, Th, Sm, or Dy).

One example of a fluorescent label is an arylsulfonate cyanine fluorescent dye as described in Mujumdar et al. (1993) *Bioconjugate Chemistry*, 4:105-111; Southwick et al. (1990) *Cytometry*, 11:418-430; and U.S. Pat. No. 5,268,486. Cy5 is a preferred arylsulfonate cyanine fluorescent dye, because it has a high extinction coefficient and good quantum yield; it also has fluorescent emission spectra in a range (500 nm to 750 nm) outside of the auto-

fluorescence wavelengths of most biological materials and plastics. In addition, Cy5 has a good solubility in water, and has low non-specific binding characteristics.

Other luminescent labels may replace fluorescent labels and be used in this invention. For example, luminescent label can be a chemiluminescent marker such as luminol (MW 177) and an acridinium ester (9[[4-[3-[(2,5-dioxo-1-pyrrolidinyl)oxy]-3-oxopropyl]phenoxy]carbonyl]-10-methyl-acridinium trifluoromethane sulfonate, MW 632). Luminescent label can also be an electrochemiluminescent marker such as ruthenium(II)tris-bipyridine (MW 1057).

A luminescent label can covalently bind to a second antibody through a variety of moieties, including disulfide, hydroxyphenyl, amino, carboxyl, indole, or other functional groups, using conventional conjugation chemistry as described in the scientific and patent literature. Exemplary techniques for binding arylsulfonate cyanine fluorescent dye labels to antibodies and other proteins are described in U.S. Pat. Nos. 5,268,486; 5,650,334; the contents of which are incorporated herein by reference. Techniques for linking a preferred Cy5 fluorescent label to antibodies are described in a technical bulletin identified as Cat. No. A25000, published by Biological Detection Systems, Inc., Pittsburgh, Pa.

In Step (c), the probe is washed 1-5 times, preferably 1-3 times in a first wash vessel containing a wash solution. The wash solution typically contains buffer and a surfactant such as Tween 20.

In step (d), the probe is moved to a read vessel and the luminescent signal of the immunocomplex bound on the probe tip is detected by the luminescent detection system as described above (e.g., see FIG. 3), where the light source and the detector are mounted at the same side (the proximal side) of the sensing surface of the probe. Alternatively, the luminescent signal can be detected by other suitable luminescent detection systems. A read vessel contains an aqueous solution such as water. A wash vessel that is used to wash the probe after sample incubation can also be used as a read vessel.

In step (e), the immunocomplex bound on the probe is eluted by employing a denaturing condition that dissociates the materials such as immune complexes bound to the probe. In general, an acid or an acidic buffer having pH about 1.5 to about 5.5 or about 2.0 to 5.5 is effective to elute the immunocomplex bound on the probe. For example, hydrochloric acid, sulfuric acid, nitric acid, acetic acid or acidic buffers can be used for elution. Depending on the analyte and the assay, an optimal pH can be about pH 2.0-3.0, 3.0-4.0, 3.5-4.5, or 4.0-5.0.

After the elution step (e), the probe tip is dipped in the read vessel and its luminescent signal (a second luminescent signal) is measured in step (f).

In step (g), the luminescent signal of eluted materials is calculated by subtracting the second luminescent signal from the first luminescent signal, and the analyte amount is  
5 determined by quantitating the luminescent signal of the eluted materials against a calibration curve (a standard curve). The calibration curve is typically pre-established before assaying the samples.

Prior to the sample binding in step (a), the luminescent signal of a probe tip is optionally pre-read by the same luminescent detection system in a read vessel. The read  
10 vessel contains an aqueous solution such as water or a buffer. Pre-read establishes a baseline of any potential background luminescent of the probe tip.

In the above steps, the reaction can be accelerated by agitating or mixing the solution in the vessel. For example, a flow such as a lateral flow or an orbital flow of the solution across the probe tip can be induced in one or more reaction vessels, including sample vessel,  
15 reagent vessel, wash vessels, and/or elution vessel, to accelerates the binding reactions, dissociation. For example, the reaction vessels can be mounted on an orbital shaker and the orbital shaker is rotated at a speed at least 50 rpm, preferably at least 200 rpm or at least 500 rpm, such as 50-200 or 500-1,500 rpm. Additionally, the probe tip can be moved up and down and perpendicular to the plane of the orbital flow, at a speed of 0.01 to 10 mm/second,  
20 in order to induce additional mixing of the solution above and below the probe tip.

In an alternative embodiment of the direct antibody binding assay, the analyte amount is determined directly from the luminescent signal of eluted materials in a liquid phase using a different optic system. The method comprises the steps of: (a) dipping a probe tip into a  
25 sample vessel containing a sample solution to bind an analyte, if present, to the first antibody on the probe tip, wherein the probe having a first antibody against the analyte immobilized on the tip of the probe; (b) dipping the probe tip into a reagent vessel containing a reagent solution comprising a second antibody against the analyte conjugated with luminescent labels to form an immunocomplex among the analyte, the first antibody, and the second antibody on  
30 the probe tip; (c) dipping the probe tip into a washing vessel containing a wash solution; (d) dipping the probe tip into an elution vessel containing an elution solution having pH 2.0-5.0 to elute materials from the probe tip; (e) removing the probe tip from the elution vessel; (f)

measuring the luminescent signal of eluted materials in the elution vessel; and determining the analyte amount.

In this alternative embodiment, steps (a)-(e) are the same as those described above in the first embodiment. After step (e), the probe is removed and the probe is no longer in the measurement step. The luminescent signal of eluted materials is measured directly from the liquid phase in the elution vessel using a luminescent detection system as described above (e.g., see FIG. 4).

### Amplification Assay

In a second aspect, the present invention is directed to a method of detecting an analyte in a liquid sample, using a binding pair and a high molecular weight polymer having multiple luminescent labels.

In a first embodiment, the luminescent signal of eluted materials is calculated by subtracting a second luminescent signal read on a probe from a first luminescent signal read on the probe. The method comprises the steps in the order of: (a) dipping a probe tip into a sample vessel containing a sample solution to bind an analyte, if present, to the first antibody on the probe tip, wherein the probe having a first antibody against the analyte immobilized on the tip of the probe; (b) dipping the probe tip into a reagent vessel containing a reagent solution comprising a reagent of a second antibody against the analyte conjugated with a first member of a binding pair to bind the reagent to the analyte; (c) dipping the probe tip into a first wash vessel containing a first wash solution to wash the probe tip; (d) dipping the probe tip into an amplification vessel containing an amplification solution comprising a crosslinked polysaccharide having a molecular weight of at least 1 million Daltons and conjugated with at least 5 molecules of second member of the binding pair and at least 25 luminescent labels, to form an immunocomplex of the analyte, the first antibody, the second antibody, and the first and the second members of the binding pair on the probe tip; (e) dipping the probe tip into a second washing vessel containing a second wash solution; (f) dipping the probe tip in a read vessel and measuring a first luminescent signal of materials bound on the probe tip; (g) dipping the probe tip into an elution solution having pH 2.0-5.0 to elute materials from the probe tip; (h) dipping the probe tip in the read vessel and measuring a second luminescent signal of materials bound on the probe tip; (i) calculating the luminescent signal of eluted materials by subtracting the second luminescent signal from the first luminescent signal, and determining the analyte amount. This assay protocol is illustrates in FIG. 6.

The second embodiment is similar to the first embodiment, except it has additional cyclic amplification steps to improve sensitivity. The method of the second embodiment further comprising a step (f') after step (f) and before (g). Step (f') is repeating steps (b) to (e) 1-10 times. This assay protocol is illustrates in FIG. 7.

5 The details of each step of amplification assay is similar to those described above for the direct antibody binding assay except steps (b) and (d), which use a binding pair and an amplification polymer.

10 The binding pair is typically a hapten and its antibody, a ligand and its receptor, complementary strands of nucleic acids, or lectin and carbohydrates. For example, the binding pair is biotin and streptavidin, biotin and avidin, biotin and neutravidin, fluorescein and anti-fluorescein, digoxigenin and anti-digoxigenin, and DNP (dinitrophenol) and anti-DNP. For example, the first member of the binding pair is biotin and the second member of the binding pair is streptavidin.

15 The amplification solution comprises a polymer conjugated with at least 5 molecules of second member of the binding pair and at least 25 luminescent labels. The polymer has a molecular weight of at least 500,000, preferably 1 million Daltons. The polymer can be a polysaccharide (e.g. FICOLL® or dextran), a polynucleotide, a dendrimer, a polyols, or polyethylene glycol. The polymer is preferably branched to have a 2- or 3- dimensional structure. The polymer preferably comprises 5-50 or 5-100 binding molecules and 25-100 or  
20 25-500 luminescent molecules.

When the binding molecule is a polypeptide or protein, the luminescent label can covalently bind to it through a variety of moieties, including disulfide, hydroxyphenyl, amino, carboxyl, indole, or other functional groups, using conventional conjugation chemistry as described in the scientific and patent literature.

25 Step (f') is cycling amplification by repeating steps (c)-(f) 1-10 times, preferably 1-5 times or 2-3 times. Each cycle consists of placing the probe back to the same reagent vessel, the same first wash vessel, the same amplification vessel, and the same second wash vessel.

For cyclic amplification, a probe with a small surface area is preferred because it has a small binding capacity. Consequently, when the probe tip is immersed in a reagent solution,  
30 the binding of the reagent does not consume a significant amount of the reagent. The reagent concentration is effectively unchanged. Negligible contamination of the wash solution and small consumption of the reagents enable the reagents and the wash solution to be re-used many times, for example, 3-10 times.

In an alternative embodiment of the amplification assay, the analyte amount is determined directly from reading the luminescent signal of eluted materials in a liquid phase using a different optic system.

5           The alternative method comprises the steps in the order of: (a) dipping a probe tip into a sample vessel containing a sample solution to bind an analyte, if present, to the first antibody on the probe tip, wherein the probe having a first antibody against the analyte immobilized on the tip of the probe; (b) dipping the probe tip into a reagent vessel containing a reagent solution comprising a reagent of a second antibody against the analyte, conjugated  
10 with a first member of a binding pair to bind the reagent to the analyte; (c) dipping the probe tip into a first wash vessel containing a first wash solution to wash the probe tip; (d) dipping the probe tip into an amplification vessel containing an amplification solution comprising a crosslinked polysaccharide having a molecular weight of at least 1 million Daltons and conjugated with at least 5 molecules of second member of the binding pair and at least 25  
15 luminescent labels, to form an immunocomplex of the analyte, the first antibody, the second antibody, and the first and the second members of the binding pair on the probe tip; (e) dipping the probe tip into a second washing vessel containing a second wash solution; (f) dipping the probe tip into an elution vessel containing an elution solution having pH 2.0-5.0 to elute materials from the probe tip; (g) removing the probe tip from the elution vessel; (h)  
20 measuring the luminescent signal of eluted materials in the elution vessel; and determining the analyte amount.

In this alternative embodiment, steps (a)-(f) are the same as those described above in the first embodiment. After step (f), the probe is removed and the probe is no longer in the measurement step. The luminescent signal of eluted materials is measured directly from the  
25 liquid phase in the elution vessel using a luminescent detection system as described above (e.g., see FIG. 4).

To improve the sensitivity, the above method can further comprising a step (e') after step (e) and before step (f). The cyclic amplification step (e') repeats steps (b) to (e) 1-10 times.

30

The invention is illustrated further by the following examples that are not to be construed as limiting the invention in scope to the specific procedures described in them.

## EXAMPLES

Examples 1-12 illustrates one embodiment of the invention, i.e., elution assays with cyclic amplification using a binding pair and crosslinked polymer highly labelled with a fluorescent dye. Example 13 illustrates another embodiment of the invention, i.e., elution assay using antibody directly labeled with a fluorescent dye.

### **Example 1: Preparation of Probe Having Immobilized First Antibody (Anti-Troponin)**

Quartz probes, 1 mm diameter and 2 cm in length, were coated with aminopropylsilane using a chemical vapor deposition process (Yield Engineering Systems, 1224P) following manufacturer's protocol. The probe tip was then immersed in a solution of murine monoclonal anti-fluorescein (Biospecific), 10 µg/ml in PBS (phosphate-buffered saline) at pH 7.4. After allowing the antibody to adsorb to the probe for 20 minutes, the probe tip was washed in PBS. These antibody-coated probes were used in Examples 1-12.

Capture antibodies for troponin I (TnI), IL-6, obtained from Biospecific, and procalcitonin (Hytest) were labeled with fluorescein by standard methods. Typically, there were about 4 fluorescein substitutions per antibody. Anti-fluorescein coated probes were immersed in fluorescein labeled capture antibody solution, 5 µg/ml, for 5 minutes followed by washing in PBS.

### **Example 2. Preparation of Crosslinked FICOLL<sup>®</sup> 400-SPDP**

To 2 ml of FICOLL<sup>®</sup> 400 (Sigma/Aldrich) that was aminated to contain 88 amines per Ficoll 400 kD (Skold Technology) at 20 mg/ml in PBS was added 10 µL of SPDP (succinimydyl 6-[3-[2-pyridyldithio]-propionamido]hexanoate, Invitrogen) at 50 mg/ml in DMF (N,N-Dimethylformamide). The SPDP to Ficoll molecular coupling ratio (MCR) was 15. The mixture reacted for 1 hour at room temperature and followed by dialysis. Thiol incorporation was estimated to be 5.5 per Ficoll 400 kD by standard methods.

### **Example 3. Preparation of Cy5- Streptavidin**

32 µL of Cy 5-NHS (GE Healthcare) at 5 mg/ml in DMF reacted with 1 ml of streptavidin (Scripps Labs) at 2.4 mg/ml in 0.1 M sodium carbonate buffer pH 9.5 for 40 minutes at 30°C. Applying the mixture to a PD 10 column (Pharmacia) removed unconjugated Cy 5. Spectral analysis indicated 2.8 Cy 5 linked per streptavidin molecule.

**Example 4. Preparation of Cy5-Streptavidin-Crosslinked FICOLL<sup>®</sup>**

5.8  $\mu$ L of SMCC (succinimidyl 4-[N-maleimidomethyl]cyclohexan-1-carboxylate) Pierce Chemical) at 10 mg/ml in DMF reacted with 2 mg Cy5-streptavidin (Example 2) in 1 ml PBS pH 7.4 for 1 hour at room temperature. Applying the mixture to a PD 10 column removed unbound SMCC.

The thiols on crosslinked FICOLL<sup>®</sup> 400-SPDP (Example 1) were deprotected by adding 30  $\mu$ L DTT at 38 mg/ml to 1 mg crosslinked FICOLL<sup>®</sup> 400-SPDP in 1 ml PBS and reacting for 1 hour at room temperature, followed by a PD 10 column to purify the crosslinked FICOLL<sup>®</sup>400-SH.

The Cy5-streptavidin-SMCC was mixed with crosslinked FICOLL<sup>®</sup> 400-SH and reacted overnight at room temperature. 10  $\mu$ L NEM (Aldrich) at 12.5 mg/ml was then added and reacted for 1/2 hour at room temperature. The conjugate was then purified on a Sepharose 4B CL column. It was estimated that the conjugate carried about 20 to 30 streptavidins per FICOLL<sup>®</sup> (2 million Daltons), and 2-3 Cy5s per streptavidin.

**Example 5: Cyclic Amplification Elution Assay Protocol and Reagents**

This example follows the general cyclic amplification protocol shown in FIG. 7. Table 1 shows the assay protocol employed for troponin (TnI), Interleukin-6 (IL-6) and procalcitonin (PCT). 20  $\mu$ L of sample were mixed with assay buffer (100  $\mu$ L PBS, 5 mg/ml BSA, 0.05% Tween 20, pH 7.4) and probe was dipped in. Wash buffer was 200  $\mu$ L PBS, 0.05% Tween 20. Antibodies for TnI (Hyttest), IL-6 (Biospecific), and PCT (Hyttest) were biotinylated (B-ab) with a standard method and used in the assay at about 5  $\mu$ g/ml in 120  $\mu$ L. The Cy5-streptavidin-FICOLL<sup>®</sup> was used at about 10  $\mu$ g/ml in 120  $\mu$ L.

**Table 1**

Step	Time (sec)	RPM (Rotation per minute)

PBS	30	1200
Read 2	/	/

#### Example 6: Effects of Elution pH from 2.0-4.0

Example 6 illustrates the effects for acidic buffers on elution, following the protocols  
 5 of Example 5. Different acid buffers were as follows: 10 mM glycine/HCl pH 2.0; 10 mM  
 glycine/HCl pH 3.0; 100 mM Na acetate/acetic acid pH 4.0.

The results are summarized in Tables 2-4. Read 1 is the fluorescence reading after  
 acid elution. "Elution" is the fluorescence reading of Read 2 subtracted from Read 1, for an  
 indirect estimate of the amount of fluorescent materials eluted from the probe. S= fluorescent  
 10 signal, B = background fluorescent signal. S/B represents the ratio of specific signal to non-  
 specific background signal. The improvement of S/B, particularly at low analyte level,  
 improves the detection level.

Table 2. PH 2

15

Tnl	Probe fluorescent Signal (v)		
	Read 1 (S/B)	Read 2 After Acid (S)	Elution (S/B) Read 1-Read 2
100 pg/ml	732 (7.9)	117	615 (14)
10 pg/ml	166 (1.8)	65	101(2.4)
0	93	50	43

**Table 3. PH 3**

Tnl	Probe fluorescent Signal (v)		
	Read 1 (S/B)	Read 2 After Acid (S)	Elution (S/B) Read 1-Read 2
100 pg/ml	624 (7.7)	88	536 (13)
10 pg/ml	181(2.2)	76	105 (2.6)
0	81	40	41

**Table 4. PH 4**

Tnl	Probe fluorescent Signal (v)		
	Read 1 (S/B)	Read 2 After Acid (S)	Elution (S/B) Read 1-Read 2
100 pg/ml	596 (8.4)	159	437 (46)
10 pg/ml	132 (1.8)	72	60 (6.0)
0	71	61	10

5           The Results of Tables 2-4 show that the amount of elution increases as the pH is lowered from 4 to 2. Taking TnI signal and dividing by the negative (0) signal determines the signal to background ratio (S/B). The results show that the S/B of elution (6.0) was about three fold better than the S/B of Read 1 (1.8) at 10 pg/ml level at pH 4.0 elution. Also, the S/B of elution (6.0) at pH 4 was better than the S/B (2.4) of at pH 2 at 10 pg/ml level.

10

**Example 7**

Example 7 illustrates the effects for acidic buffers on elution from pH 4 to 5.5, following the protocols of Example 5. Different acid buffers were as follows: 100 mM Na acetate/ acetic acid pH 4.0; 100 mM Na acetate/acetic acid pH 5.0; 100mM Na acetate/acetic acid pH 5.5.

15

**Table 5. PH 4**

Tnl	Probe fluorescent Signal (v)		
	Read 1 (S/B)	Read 2 After Acid (S)	Elution (S/B) Read 1-Read 2
100 pg/ml	2044 (29)	258	1786 (64)
10 pg/ml	290 (4)	54	236 (8)
0	70.5	43	28

**Table 6. PH 5**

Tnl	Probe fluorescent Signal (v)		
	Read 1 (S/B)	Read 2 After Acid (S)	Elution (S/B) Read 1-Read 2
100 pg/ml	1796 (29)	1301	495 (35)
10 pg/ml	233 (4)	150	83 (6)
0	61	47	14

**5 Table 7. PH 5.5**

Tnl	Probe fluorescent Signal (v)		
	Read 1 (S/B)	Read 2 After Acid (S)	Elution (S/B) Read 1-Read 2
100 pg/ml	1802 (23)	1147	655 (28)
10 pg/ml	249 (3)	143	106 (5)
0	79	56	23

Tables 5-7 show that the S/B of elution were all improved over the S/B of read 1. Around pH 4.0 appears to be optimal for S/B for cyclic amplification assay for troponin.

**Example 8: Limit of Detection for Troponin Assay**

Limit of blank (LOB) is defined as mean blank + 1.645 x (SD blank)

Limit of detection (LOD) is defined as LOB + 1.645 x (SD blank)

SD is standard deviation.

5 (David et al., Clin. Biochem. Rev. 29: S49-52)

Following the elution protocol of troponin with pH 4.0 acid treatment of Example 5, LOD was determined by Read 1 (one read only, no acid elution) and Read 2 (elution assay with acid elution). LOD was 2.9 pg/mL by read 1, and was improved to 1.3 pg/mL by elution assay.

10

**Example 9: Detection Troponin in Normal Samples**

Following the elution protocol of troponin of Example 5 at pH 4, 39 heparin plasma samples from 39 apparently normal individuals were measured for troponin level by direct assay (Read 1, no acid elution) and elution assay (Read 2, with acid elution). The troponin levels of 100% of the 39 normal samples were detected with elution assay, while only 46% were detected with Read 1.

15

The results show that the benefits of the elution assay of this invention apply to detecting TnI within the normal range.

20

**Example 10: HsTnI Designation**

Following the elution protocol of troponin of Example 8, 611 normal serum samples were detected for troponin levels.

The elution protocol detected 91% in the 611 normal serum samples tested, which falls in the 2<sup>nd</sup> generation hsTnI designation. The 99<sup>th</sup> percentile was 36 pg/mL with a between run CV of 10%, which is acceptable according to TnI Designation Guideline (see FIG. 1).

25

**Example 11: IL-6 Assay**

IL-6 is another analyte requiring high sensitivity measurements. Table 8 shows data for IL-6 follows the protocols of Example 6, using pH 4.0 acid elution.

30

**Table 8**

IL-6	Probe fluorescent Signal (v)		
	Read 1 (S/B)	Read 2 After Acid (S)	Elution (S/B) Read 1-Read 2
5000 pg/mL	5819 (65.4)	1684	4136 (133.4)
2500 pg/mL	3254 (36.6)	526	2728 (88.0)
500 pg/mL	758 (8.5)	100	659 (21.2)
250 pg/mL	426 (4.8)	73	353 (11.4)
50 pg/mL	149 (1.7)	56	93 (3.0)
25 pg/mL	108 (1.2)	47	61 (2.0)
0	89 (1.0)	58	31 (1.0)

The results in Table 8 shows that elution protocol generates about a 2 fold improvement in S/B ratio comparing with no elution, and the elution protocol detected 25 pg/mL level in IL-6 assay.

#### **Example 12: Procalcitonin Assay, Alternative Optical Detection Configurations**

Table 9 shows the protocols of PCT assay, using pH 4.0 acid elution. Fluorescent signals were measured with an alternative optical detection configuration. The optics with a wide laser beam and numerical aperture of the collecting lens directly detect the eluted labeled antibody in fluid phase.

**Table 9**

5

**Example 13. Direct Antibody Assay of C-Reactive Protein (CRP)**

Example 13 illustrates another embodiment of the invention, i.e., elution assay using antibody directly labeled with a fluorescent dye, and without cyclic amplification. The assay follows the general protocols as shown in FIG. 5.

10

**Preparation of Probe Having Immobilized First Antibody (Anti-CRP)**

Quartz probes, 1 mm diameter and 2 cm in length, were coated with aminopropylsilane using a chemical vapor deposition process (Yield Engineering Systems, 1224P ) following manufacturer's protocol. The probe tip was then immersed in a solution of streptavidin (Sigma-Aldrich), 10  $\mu\text{g/mL}$  in phosphate-buffered saline pH 7.4 (PBS). After allowing the protein to adsorb to the probe for 5 minutes, the probe tip was washed in PBS. The probe tip was then immersed in a solution containing a biotin-labeled anti-CRP (Hytest) at 10  $\mu\text{g/mL}$  in PBS. After 10 minutes, the probe tip was washed in PBS. The antibody was

15

biotinylated by a standard method. The biotinylated antibody were designated as “capture antibody”.

**Preparation of CY5 Labeled Antibody**

5 Anti-CRP (Hytest) at 3.2 mg/mL in 1 ml 0.1 M sodium carbonate pH 9.5 was mixed with 10.6 µL of Cy5-NHS (GE Healthcare) at 10 mg/ml in DMF and allowed to reacted for ½ hour at 30°C. The mixture was then purified on a PD 10 column (GE Healthcare). The Cy5 labeled antibody was designated as “signal antibody”.

10 CRP Assay Protocol is shown in Table 11.

**Table 11**

Step	Time (sec)	RPM
Pre-read	0	1200
CRP sample (120 µL)	15	1200
3x wash (150 µL)	3 x 7	1200
Cy5-antiCRP (120 µL)	15	1200
3x wash (150 µL)	3 x 7	1200
Read 1	0	0
pH 2	10	1200
Read 2	0	0

CRP Results are shown in Table 12.

**Table 12**

CRP	Probe fluorescent Signal (v)		
	Read 1 (S/B)	Read 2 After Acid (S)	Elution (S/B) Read 1-Read 2
10 mg/L	484 (35)	13	471 (471)
3 mg/L	171 (12)	13	158 (158)
1 mg/L	83.5 (6)	14	70 (70)
0	14	13	1

15

The results show that elution protocol improves the signal to background ratio from 6 to 70 at the CRP level of 1 mg/L.

5 The invention, and the manner and process of making and using it, are now described in such full, clear, concise and exact terms as to enable any person skilled in the art to which it pertains, to make and use the same. It is to be understood that the foregoing describes preferred embodiments of the present invention and that modifications may be made therein without departing from the scope of the present invention as set forth in the claims. To particularly point out and distinctly claim the subject matter regarded as invention, the  
10 following claims conclude this specification.

**WHAT IS CLAIMED IS:**

1. A method of detecting an analyte in a liquid sample, comprising the steps of:
  - (a) dipping a probe tip into a sample vessel containing a sample solution to bind an analyte, if present, to the first antibody on the probe tip, wherein the probe having a first antibody against the analyte immobilized on the tip of the probe;
  - (b) dipping the probe tip into a reagent vessel containing a reagent solution comprising a second antibody against the analyte, conjugated with luminescent labels to form an immunocomplex among the analyte, the first antibody, and the second antibody on the probe tip;
  - (c) dipping the probe tip into a washing vessel containing a wash solution;
  - (d) dipping the probe tip in a read vessel and measuring a first luminescent signal of materials bound on the probe tip;
  - (e) dipping the probe tip into an elution solution having pH 2.0-5.0 to elute materials from the probe tip;
  - (f) dipping the probe tip in the read vessel and measuring a second luminescent signal of materials bound on the probe tip;
  - (g) calculating the luminescent signal of eluted materials by subtracting the second luminescent signal from the first luminescent signal, and determining the analyte amount.
  
2. A method of detecting an analyte in a liquid sample, comprising the steps of:
  - (a) dipping a probe tip into a sample vessel containing a sample solution to bind an analyte, if present, to the first antibody on the probe tip, wherein the probe having a first antibody against the analyte immobilized on the tip of the probe;
  - (b) dipping the probe tip into a reagent vessel containing a reagent solution comprising a second antibody against the analyte conjugated with luminescent labels to form an immunocomplex among the analyte, the first antibody, and the second antibody on the probe tip;
  - (c) dipping the probe tip into a washing vessel containing a wash solution;
  - (d) dipping the probe tip into an elution vessel containing an elution solution having pH 2.0-5.0 to elute materials from the probe tip;
  - (e) removing the probe tip from the elution vessel;
  - (f) measuring the luminescent signal of eluted materials in the elution vessel and determining the analyte amount.

3. A method of detecting an analyte in a liquid sample, comprising the steps in the order of:
  - (a) dipping a probe tip into a sample vessel containing a sample solution to bind an analyte, if present, to the first antibody on the probe tip, wherein the probe having a first antibody against the analyte immobilized on the tip of the probe;
  - (b) dipping the probe tip into a reagent vessel containing a reagent solution comprising a reagent of a second antibody against the analyte conjugated with a first member of a binding pair to bind the reagent to the analyte;
  - (c) dipping the probe tip into a first wash vessel containing a first wash solution to wash the probe tip;
  - (d) dipping the probe tip into an amplification vessel containing an amplification solution comprising a crosslinked polysaccharide having a molecular weight of at least 1 million Daltons and conjugated with at least 5 molecules of second member of the binding pair and at least 25 luminescent labels, to form an immunocomplex of the analyte, the first antibody, the second antibody, and the first and the second members of the binding pair on the probe tip;
  - (e) dipping the probe tip into a second washing vessel containing a second wash solution;
  - (f) dipping the probe tip in a read vessel and measuring a first luminescent signal of materials bound on the probe tip;
  - (g) dipping the probe tip into an elution solution having pH 2.0-5.0 to elute materials from the probe tip;
  - (h) dipping the probe tip in the read vessel and measuring a second luminescent signal of materials bound on the probe tip;
  - (i) calculating the luminescent signal of eluted materials by subtracting the second luminescent signal from the first luminescent signal, and determining the analyte amount.
4. The method according to Claim 3, further comprising a step (f') after step (f) and before (g):
  - (f') repeating steps (b) to (e) 1-10 times.

5. A method of detecting an analyte in a liquid sample, comprising the steps in the order of:
- (a) dipping a probe tip into a sample vessel containing a sample solution to bind an analyte, if present, to the first antibody on the probe tip, wherein the probe having a first antibody against the analyte immobilized on the tip of the probe;
  - (b) dipping the probe tip into a reagent vessel containing a reagent solution comprising a reagent of a second antibody against the analyte, conjugated with a first member of a binding pair to bind the reagent to the analyte;
  - (c) dipping the probe tip into a first wash vessel containing a first wash solution to wash the probe tip;
  - (d) dipping the probe tip into an amplification vessel containing an amplification solution comprising a crosslinked polysaccharide having a molecular weight of at least 1 million Daltons and conjugated with at least 5 molecules of second member of the binding pair and at least 25 luminescent labels, to form an immunocomplex of the analyte, the first antibody, the second antibody, and the first and the second members of the binding pair on the probe tip;
  - (e) dipping the probe tip into a second washing vessel containing a second wash solution;
  - (f) dipping the probe tip into an elution vessel containing an elution solution having pH 2.0-5.0 to elute materials from the probe tip;
  - (g) removing the probe tip from the elution vessel;
  - (h) measuring the luminescent signal of eluted materials in the elution vessel and determining the analyte amount.
6. The method according to Claim 5, further comprising a step (e') after step (e) and before step (f):
- (e') repeating steps (b) to (e) 1-10 times.
7. The method according to any one of Claims 1-6, wherein the tip surface is  $\leq$  about 5 mm.
8. The method according to any one of Claims 1-6, wherein the luminescent label is a fluorescent label.

9. The method according to Claim 8, wherein the fluorescent label is arylsulfonate cyanine.
10. The method according to Claim 1-6, wherein the luminescent label is a molecule selected from the group consisting of: ruthenium(II)tris-bipyridine, luminol, and an acridinium ester.
11. The method according to any one of Claims 3-6, wherein the first member of the binding pair is biotin and the second member of the binding pair is streptavidin.
12. The method according to any one of Claims 3-6, wherein the polysaccharide is a copolymers of sucrose and epichlorohydrin.
13. The method according to any one of Claims 3-6, wherein the analyte is troponin.

* Special categories of cited documents:		
"A"	document defining the general state of the art which is not considered to be of particular relevance	"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"E"	earlier document but published on or after the international filing date	"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"L"	document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"O"	document referring to an oral disclosure, use, exhibition or other means	"&" document member of the same patent family
"P"	document published prior to the international filing date but later than the priority date claimed

#### 摘要(译)

本发明涉及增加免疫测定灵敏度的方法。本发明利用酸洗脱条件，其优先洗脱特异性结合的免疫复合物而不是来自固相的非特异性结合的复合物，并设计免疫测定方案，其改善特异性结合与非特异性结合的比率，从而提高测定灵敏度。该方案确定从固相洗脱的标记免疫复合物的信号。
