(54) Title: METHODS OF DIAGNOSING AND TREATING PRE-ECLAMPSIA OR ECLAMPSIA

(57) Abstract: Disclosed herein are methods for treating pre-eclampsia or eclampsia using compounds that increase VEGF or PlGF levels or compounds that decrease sFlt-1 levels. Also disclosed here in are methods for monitoring the treatment of pre-eclampsia or eclampsia by detecting the levels of sFlt-1, VEGF, or PlGF. Also disclosed herein are methods for diagnosing pre-eclampsia and eclampsia by detecting the levels of sFlt-1, VEGF, and PlGF in a subject.

WO 2005/077007 A2

5

METHODS OF DIAGNOSING AND TREATING PRE-ECLAMPSIA OR ECLAMPSIA

Field of the Invention

In general, this invention relates to the detection and treatment of subjects
10 having pre-eclampsia or eclampsia.

Background of the Invention

Pre-eclampsia is a syndrome of hypertension, edema, and proteinuria that
affects 5 to 10% of pregnancies and results in substantial maternal and fetal morbidity
15 and mortality. Pre-eclampsia accounts for at least 200,000 maternal deaths worldwide
per year. The symptoms of pre-eclampsia typically appear after the 20th week of
pregnancy and are usually detected by routine monitoring of the woman's blood
pressure and urine. However, these monitoring methods are ineffective for diagnosis
of the syndrome at an early stage. Such early detection could reduce the risk to the
20 subject or developing fetus, if an effective treatment were available.

Currently there are no known cures for pre-eclampsia. Pre-eclampsia can vary
in severity from mild to life-threatening. A mild form of pre-eclampsia can be treated
with bed rest and frequent monitoring. For moderate to severe cases, hospitalization
is required and blood pressure medication or anticonvulsant medications to prevent
25 seizures are administered. If the condition becomes life-threatening to the mother or
the baby the pregnancy is terminated and the baby is delivered pre-term.

The proper development of the fetus and the placenta is mediated by several
growth factors. One of these growth factors is vascular endothelial growth factor
(VEGF). VEGF is an endothelial cell-specific mitogen, an angiogenic inducer, and a
30 mediator of vascular permeability. VEGF has also been shown to be important for
glomerular capillary repair. VEGF binds as a homodimer to one of two homologous
membrane-spanning tyrosine kinase receptors, the fms-like tyrosine kinase (Flt-1) and
the kinase domain receptor (KDR), which are differentially expressed in endothelial
cells obtained from many different tissues. Flt-1, but not KDR, is highly expressed by
35 trophoblast cells which contribute to placental formation. Placental growth factor

(PlGF) is a VEGF family member that is also involved in placental development. PlGF is expressed by cytotrophoblasts and syncytiotrophoblasts and is capable of inducing proliferation, migration, and activation of endothelial cells. PlGF binds as a homodimer to the Flt-1 receptor, but not the KDR receptor. Both PlGF and VEGF contribute to the mitogenic activity and angiogenesis that are critical for the developing placenta.

A soluble form of the Flt-1 receptor (sFlt-1) was recently identified in a cultured medium of human umbilical vein endothelial cells and *in vivo* expression was subsequently demonstrated in placental tissue. sFlt-1 is a splice variant of the Flt-1 receptor which lacks the transmembrane and cytoplasmic domains. sFlt-1 binds to VEGF with a high affinity but does not stimulate mitogenesis of endothelial cells. sFlt-1 is believed to act as a "physiologic sink" to down-regulate VEGF signaling pathways. Regulation of sFlt-1 levels therefore works to modulate VEGF and VEGF signaling pathways. Careful regulation of VEGF and PlGF signaling pathways is critical for maintaining appropriate proliferation, migration, and angiogenesis by trophoblast cells in the developing placenta. There is a need for methods of accurately diagnosing subjects at risk for or having pre-eclampsia, particularly before the onset of the most severe symptoms. A treatment is also needed.

Summary of the Invention

We have discovered a means for diagnosing and effectively treating pre-eclampsia and eclampsia.

Using gene expression analysis, we have discovered that levels of sFlt-1 are markedly elevated in placental tissue samples from pregnant women suffering from pre-eclampsia. sFlt-1 is known to antagonize VEGF and PlGF by acting as a "physiologic sink" and, in pre-eclamptic or eclamptic women, sFlt-1 may be depleting the placenta of necessary amounts of these essential angiogenic and mitogenic factors. Excess sFlt-1 may also lead to eclampsia by disrupting the endothelial cells that maintain the blood-brain barrier and/or endothelial cells lining the choroids plexus of the brain thus leading to cerebral edema and the seizures seen in eclampsia. In the present invention, compounds that increase VEGF and PlGF levels are administered to a subject to treat or prevent pre-eclampsia or eclampsia by countering the effects of elevated sFlt-1. In addition, antibodies directed to sFlt-1 are used to competitively

inhibit binding of VEGF or PlGF to sFlt-1, thereby increasing the levels of free VEGF and PlGF. RNA interference and antisense nucleobase oligomers are also used to decrease the levels of sFlt-1. The present invention also provides for the use and monitoring of sFlt-1, VEGF, and PlGF as detection tools for early diagnosis and management of pre-eclampsia or eclampsia, or a predisposition thereto, or a cardiovascular condition, or a predisposition thereto.

We have also discovered that PlGF levels in the urine can be used as a diagnostic tool to detect pre-eclampsia or eclampsia, or a predisposition thereto. The free form of PlGF has an average molecular weight of about 30 kDa and is small enough to be filtered by the kidney and released into the urine. PlGF, when complexed to sFlt-1, has a much greater molecular weight and would therefore not be released into the urine. When the levels of sFlt-1 are increased, sFlt-1 can complex to PlGF, thereby reducing the levels of free PlGF released into the urine. As a result, urine analysis for free PlGF levels can be used to diagnose pre-eclampsia or eclampsia or a patient at risk for having the same.

Accordingly, in one aspect, the invention provides a method of treating or preventing pre-eclampsia or eclampsia in a subject by administering to the subject a compound capable of binding to sFlt-1, where the administering is for a time and in an amount sufficient to treat or prevent pre-eclampsia or eclampsia in a subject. In a preferred embodiment, the compound is a purified sFlt-1 antibody or antigen-binding fragment thereof.

In a related aspect, the invention provides a method of treating or preventing pre-eclampsia or eclampsia in a subject by administering to the subject a compound (e.g., nicotine, theophylline, adenosine, nifedipine, minoxidil, or magnesium sulfate) that increases the level of a growth factor capable of binding to sFlt-1, where the administering is for a time and in an amount sufficient to treat or prevent pre-eclampsia or eclampsia in a subject.

In yet another related aspect, the invention provides a method of treating or preventing pre-eclampsia or eclampsia in a subject by administering to the subject an antisense nucleobase oligomer complementary to at least a portion of an sFlt-1 nucleic acid sequence, where the administering is sufficient to treat or prevent pre-eclampsia or eclampsia in a subject. In one embodiment, the antisense nucleobase oligomer is 8 to 30 nucleotides in length.

In another related aspect, the invention provides a method of treating or preventing pre-eclampsia or eclampsia in a subject by administering to the subject a double stranded RNA (dsRNA) that contains at least a portion of an sFlt-1 nucleic acid sequence, where the administering is sufficient to treat or prevent pre-eclampsia or eclampsia in the subject. In one embodiment, the double stranded RNA is processed into small interfering RNAs (siRNAs) 19 to 25 nucleotides in length.

In various embodiments of the above aspects, the candidate compound is a growth factor such as vascular endothelial growth factor (VEGF), including all isoforms such as VEGF189, VEGF121, or VEGF165; placental growth factor (PlGF), including all isoforms; or fragments thereof, and modified forms of VEGF or PlGF. In preferred embodiments, the candidate compound is an antibody that binds sFlt-1. In other embodiments of the above aspects, the method further involves administering to a subject an anti-hypertensive compound. In still other embodiments of the above aspects, the subject is a pregnant human, a post-partum human, or a non-human (e.g., a cow, a horse, a sheep, a pig, a goat, a dog, or a cat).

In another aspect, the invention provides a method of treating or preventing pre-eclampsia or eclampsia by administering to a subject in need of such treatment an effective amount of a pharmaceutical composition comprising a VEGF or PlGF polypeptide. In one embodiment, the composition contains a VEGF polypeptide. In another embodiment, the composition contains a PlGF polypeptide.

In a related aspect, the invention provides a method of treating or preventing pre-eclampsia or eclampsia by administering to a subject in need of such treatment an effective amount of a pharmaceutical composition comprising a nucleic acid molecule encoding VEGF or PlGF. In one embodiment, the composition contains a VEGF nucleic acid molecule. In another embodiment, the composition contains a PlGF nucleic acid molecule.

In another related aspect, the invention provides a method of treating or preventing pre-eclampsia or eclampsia in a subject. The method involves the step of administering to the subject a compound (e.g., chemical compound, polypeptide, peptide, antibody, or a fragment thereof) that inhibits growth factor binding to an sFlt-1 polypeptide, where the administering is sufficient to treat or prevent pre-eclampsia or eclampsia in a subject. In one embodiment, the compound binds to sFlt-1 and blocks growth factor binding.

In various embodiments of the above aspects, the method further involves the step of administering to a subject an anti-hypertensive compound (e.g., adenosine, nifedipine, minoxidil, and magnesium sulfate). In other embodiments of the above aspects, the subject is a pregnant human, a post-partum human, or a non-human (e.g.,
5 a cow, a horse, a sheep, a pig, a goat, a dog, or a cat).

In another aspect, the invention features a method of diagnosing a subject as having, or having a propensity to develop, pre-eclampsia or eclampsia that includes measuring the level of free PlGF in a urine sample from the subject. This method can be used to determine absolute levels of free PlGF that are below a threshold level and
10 are diagnostic of pre-eclampsia or eclampsia or the propensity to develop pre-eclampsia or eclampsia. The normal urinary concentration of urinary PlGF is approximately 400-800 pg/ml during mid-pregnancy. In preferred embodiments, a level of free PlGF less than 400 pg/ml, preferably less than 300, 200, 100, 50, or 10 pg/ml is diagnostic of pre-eclampsia or eclampsia or the propensity to develop pre-
15 eclampsia or eclampsia. This method can also be used to determine relative levels of free PlGF as compared to a reference sample where a decrease (e.g., 10%, 20%, 25%, 50%, 75%, 90%, or more) in the level of free PlGF as compared to a normal reference sample is diagnostic of pre-eclampsia or eclampsia or the propensity to develop pre-
20 eclampsia or eclampsia. In this case, the normal reference sample can be a prior sample taken from the same subject or a sample taken from a matched subject (e.g., matched for gestational age) that is pregnant but does not have pre-eclampsia or eclampsia or a propensity to develop pre-eclampsia or eclampsia. In additional preferred embodiments, the reference sample is a standard, level, or number derived from such a normal reference sample. The reference standard or level can also be a
25 value derived from a normal subject that is matched to the sample subject by at least one of the following criteria: gestational age of the fetus, age of the mother, blood pressure prior to pregnancy, blood pressure during pregnancy, BMI of the mother, weight of the fetus, prior diagnosis of pre-eclampsia or eclampsia, and a family history of pre-eclampsia or eclampsia. In preferred embodiments, the measuring is
30 done using an immunological assay such as an ELISA, preferably a sandwich ELISA, or a fluorescence immunoassay.

In preferred embodiments, the method also includes the steps of (a) measuring the level of at least one of sFlt-1, PlGF, and VEGF polypeptide in a sample from the subject, where the sample is a bodily fluid selected from the group consisting of urine, blood, amniotic fluid, serum, plasma, or cerebrospinal fluid, and (b) comparing the level of at least one of sFlt-1, PlGF, and VEGF from the subject to the level of the same polypeptide in a reference sample, where an increase in the level of sFlt-1 or a decrease in the level of VEGF or PlGF polypeptide from the subject sample compared to the reference sample is a diagnostic indicator of pre-eclampsia or eclampsia, or a propensity to develop pre-eclampsia or eclampsia. In preferred embodiments, sFlt-1 or sFlt-1 and PlGF are measured in a serum sample from a subject identified by a urine PlGF assay as being at risk for developing pre-eclampsia or eclampsia. Desirably, this method further includes calculating the relationship between the levels of at least one of sFlt-1, VEGF, and PlGF from step (a) above using a metric, where an alteration in the subject sample relative to the metric in the reference sample diagnoses pre-eclampsia or eclampsia or a propensity to develop pre-eclampsia or eclampsia. Preferably, the metric is a PAAI (as described above) and a PAAI value greater than 20 is a diagnostic indicator of pre-eclampsia or eclampsia. In preferred embodiments, the sFlt-1 is free, bound, or total sFlt-1, and the PlGF and VEGF are free PlGF and free VEGF.

In another aspect, the invention features a method of diagnosing a subject as having or having a propensity to develop pre-eclampsia or eclampsia that includes the following steps:

- (a) obtaining a sample of urine from the subject;
- (b) contacting the sample with a solid support, where the solid support includes an immobilized first PlGF binding agent, for a time sufficient to allow binding of the first PlGF binding agent with free PlGF present in the sample;
- (c) contacting the solid support after step (b) with a preparation of a second labeled PlGF binding agent, for a time sufficient to allow binding of the second labeled PlGF binding agent to the free PlGF bound to the first immobilized PlGF binding agent;
- (d) observing the binding of the second labeled PlGF binding agent to the immobilized PlGF binding agent bound to free PlGF at the position where the PlGF binding agent is immobilized; and

(e) comparing the binding observed in step (d) with the binding observed using a reference sample, where the reference sample is PlGF at a known concentration; and further where a decrease in the binding observed in step (d) compared to the binding observed using a reference sample is a diagnostic indicator of pre-eclampsia or eclampsia or a propensity to develop pre-eclampsia or eclampsia.

In another related aspect, the invention features a method of diagnosing a subject as having or having a propensity to develop pre-eclampsia or eclampsia, that includes the following steps:

(a) obtaining a urine sample from the subject;

10 (b) contacting the urine sample with a solid support, wherein the solid support comprises a dehydrated labeled PlGF binding agent and an immobilized secondary agent that binds the PlGF binding agent, for a time sufficient for the sample to rehydrate the labeled PlGF binding agent and to allow binding of free PlGF in the sample to the labeled PlGF binding agent, wherein the free PlGF bound to the labeled

15 PlGF binding agent can move (e.g., by capillary movement) to the immobilized secondary agent;

(c) observing the binding of the free PlGF-PlGF binding agent complex to the immobilized secondary agent by detecting the presence of the label at the position where the secondary agent is immobilized; and

20 (d) comparing the binding observed in step (c) with the binding observed using a reference sample, wherein the reference sample is PlGF at known concentrations ranging from 10 pg/ml -1ng/ml.

In preferred embodiments of the above two aspects, the label is a colorimetric label (e.g., colloidal gold). In additional preferred embodiments, the agent that binds

25 PlGF is an antibody, or purified fragment thereof, or a peptide. Desirably, the antibody or purified fragment thereof specifically binds free PlGF. The agent that binds a PlGF agent is desirably an anti-immunoglobulin antibody or fragment thereof, protein A, or protein G. In one embodiment, the reference sample is a PlGF sample at a known normal concentration and a decrease in the free PlGF in the subject sample

30 as compared to the reference sample is diagnostic of pre-eclampsia or eclampsia or a propensity to develop pre-eclampsia or eclampsia.

In another aspect, the invention features a method of diagnosing a subject as having or having a propensity to develop pre-eclampsia or eclampsia that includes the following steps:

- (a) obtaining a urine sample from the subject;
- 5 (b) contacting the sample with a solid support having an immobilized PlGF binding agent that is detectably labeled in a manner such that the label can distinguish between the PlGF when it is bound to free PlGF and when it is not bound to free PlGF. Preferred labels include fluorescent labels. The membrane is exposed to a urine sample obtained from the subject for a time sufficient to allow binding of the
- 10 PlGF binding agent to free PlGF present in the sample. The labeled PlGF binding agent bound to the free PlGF is then measured. Such an assay can be used to determine the relative level of PlGF (e.g., as compared to the level from a reference sample or standard or level) or to determine the absolute concentration of PlGF as described above. Preferred assays for the measurement of binding include
- 15 fluorescence immunoassays.

In another aspect the invention features a method of diagnosing a subject as having or having a propensity to develop pre-eclampsia or eclampsia that includes the following steps:

- (a) obtaining a urine sample from the subject;
- 20 (b) contacting the sample with a solid support, wherein the solid support comprises an immobilized first PlGF binding agent, for a time sufficient to allow binding of the first PlGF binding agent with free PlGF present in the sample;
- (c) contacting the solid support after step (b) with a preparation of a second PlGF binding agent coupled to an enzyme, for a time sufficient to allow binding of the
- 25 second PlGF binding agent to the PlGF bound to the first immobilized PlGF binding agent; and
- (d) adding a preparation of a substrate for the enzyme of step (c), for a time and in an amount sufficient to allow the enzyme to convert the substrate to a detectable substrate;
- 30 (e) observing the level of the detectable substrate; and
- (f) comparing the level observed in step (e) with the binding observed using a reference sample, wherein the reference sample is PlGF at a known concentration,

wherein an alteration in the level observed in step (e) as compared to the reference sample is a diagnostic indicator of pre-eclampsia or eclampsia or a propensity to develop pre-eclampsia or eclampsia.

In one embodiment, the reference sample is a PlGF sample at a known normal concentration and a decrease in the free PlGF in the subject sample as compared to the reference sample is diagnostic of pre-eclampsia or eclampsia or a propensity to develop pre-eclampsia or eclampsia.

In preferred embodiments of the above method, the substrate is detected visually, by spectrophotometry or by chemiluminescence. In additional preferred embodiments, the enzyme is horseradish peroxidase, β -galactosidase, or alkaline phosphatase and the substrate is TMB (tetramethylbenzidine), Xgal (5-bromo-4-chloro-3-indolyl- β -D-galactopyranoside), or 1,2 dioxetane. In additional preferred embodiments, the reference sample is a sample having a normal concentration of purified PlGF and the subject sample shows a decrease (10%, 25%, 50%, 75%, 90% or more) compared to the reference sample. In preferred embodiments of this method, the PlGF binding agent is a purified anti-PlGF antibody, or fragment thereof, or a peptide. Desirably, the purified anti-PlGF antibody, or fragment thereof specifically binds free PlGF.

In preferred embodiments of any of the above diagnostic methods, the solid support is a membrane that can be supported on a dipstick structure or a lateral flow format, examples of which are described in U.S.P.N. 6,660,534. In additional preferred embodiments, the subject is a non-pregnant human, a pregnant human, or a post-partum human. In other embodiments of the above aspects, the subject is a non-human (e.g., a cow, a horse, a sheep, a pig, a goat, a dog, or a cat). In one embodiment, the subject is a non-pregnant human and the method is used to diagnose a propensity to develop pre-eclampsia or eclampsia. In another embodiment, the subject is a human (pregnant or non-pregnant) with a history of pre-eclampsia and the method is used to diagnose a propensity to develop pre-eclampsia or eclampsia in a subsequent pregnancy. Desirably, the measuring of levels is done on two or more occasions and a change in the levels between measurements is a diagnostic indicator of pre-eclampsia or eclampsia.

In additional preferred embodiments, the methods to detect PlGF levels in a urine sample from a subject can be combined with any of the diagnostic methods described below used to measure the level of sFlt-1, PlGF, or VEGF nucleic acid or polypeptide.

5 In another aspect, the invention provides a method of diagnosing a subject as having, or having a propensity to develop, pre-eclampsia or eclampsia, the method involves measuring the level of sFlt-1, VEGF, or PlGF polypeptide in a sample from the subject.

In a related aspect, the invention provides a method of diagnosing a subject as
10 having, or having a propensity to develop, pre-eclampsia or eclampsia, by determining the levels of at least two of sFlt-1, VEGF, or PlGF polypeptide in a sample from a subject and calculating the relationship between the levels of sFlt-1 VEGF, or PlGF using a metric, where an alteration in the subject sample relative to a reference diagnoses pre-eclampsia or eclampsia in a subject. In preferred
15 embodiments, the method also includes determining the body mass index (BMI), the gestational age (GA) of the fetus, or both and including the BMI or GA or both in the metric. In one embodiment, the metric is a pre-eclampsia anti-angiogenic index (PAAI): $[sFlt-1/VEGF + PlGF]$, where the PAAI is used as an indicator of anti-angiogenic activity. In one embodiment, a PAAI greater than 10, more preferably
20 greater than 20, is indicative of pre-eclampsia or eclampsia. In another embodiment, the levels of sFlt-1, VEGF, or PlGF polypeptide is determined by an immunological assay, such as an ELISA.

In various embodiments of the above aspects, the sample is a bodily fluid, such as serum or urine. In one embodiment, a level of sFlt-1 greater than 2 ng/ml is
25 indicative of pre-eclampsia or eclampsia. In preferred embodiments of the above aspects, the level of sFlt-1 polypeptide measured is the level of free, bound, or total sFlt-1 polypeptide. In additional embodiments, the sFlt-1 polypeptide can also include sFlt-1 fragments or polypeptide by-products resulting from degradation or enzymatic cleavage of sFlt-1. In other preferred embodiments of the above aspects,
30 the level of VEGF or PlGF is the level of free VEGF or PlGF.

In another aspect, the invention provides a method of diagnosing a subject as having, or having a propensity to develop, pre-eclampsia or eclampsia that includes measuring the level of sFlt-1, VEGF, or PlGF nucleic acid molecule in a sample from

the subject and comparing it to a reference sample, where an alteration in the levels diagnoses pre-eclampsia or eclampsia in the subject, or diagnoses a propensity to develop pre-eclampsia or eclampsia.

In another aspect, the invention provides a method of diagnosing a subject as
5 having, or having a propensity to develop, pre-eclampsia or eclampsia by determining the nucleic acid sequence of a sFlt-1, VEGF, or PlGF gene in a subject and comparing it to a reference sequence, where an alteration in the subject's nucleic acid sequence that changes the level or the biological activity of the gene product in the subject diagnoses the subject with pre-eclampsia or eclampsia, or a propensity to develop pre-
10 eclampsia or eclampsia. In one embodiment, the alteration is a polymorphism in the nucleic acid sequence.

In various embodiments of any of the above aspects, the sample is a bodily fluid (e.g., urine, amniotic fluid, serum, plasma, or cerebrospinal fluid) of the subject in which the sFlt-1, VEGF, or PlGF is normally detectable. In additional
15 embodiments, the sample is a tissue or a cell. Non-limiting examples include placental tissue or placental cells, endothelial cells, leukocytes, and monocytes. In other embodiments of the above aspects, the subject is a non-pregnant human, a pregnant human, or a post-partum human. In other embodiments of the above aspects, the subject is a non-human (e.g., a cow, a horse, a sheep, a pig, a goat, a dog,
20 or a cat). In one embodiment, the subject is a non-pregnant human and the method is used to diagnose a propensity to develop pre-eclampsia or eclampsia. In other embodiments of the above aspects, at least one of the levels measured is the level of sFlt-1 (free, bound, or total). In additional embodiments, the level of sFlt-1 measured includes the level of sFlt-1 degradation products or enzymatic cleavage products. In
25 other embodiments of the above aspects, when the level of VEGF is measured then the level of sFlt-1 or PlGF is also measured. In additional embodiments, the BMI or GA or both is also measured. In various embodiments of the above aspects, an increase in the level of sFlt-1 nucleic acid or polypeptide relative to a reference is a diagnostic indicator of pre-eclampsia or eclampsia. In other embodiments of the
30 above aspects, a decrease in the level of free VEGF polypeptide or VEGF nucleic acid relative to a reference is a diagnostic indicator of pre-eclampsia or eclampsia. In

other embodiments of the above aspects, a decrease in the level of free PlGF polypeptide or PlGF nucleic acid relative to a reference is a diagnostic indicator of pre-eclampsia or eclampsia.

In additional embodiments of the above aspects, the levels are measured on
5 two or more occasions and a change in the levels between the measurements is a diagnostic indicator of pre-eclampsia or eclampsia. In one preferred embodiment, the level of sFlt-1 increases from the first measurement to the next measurement. In another preferred embodiment, the level of VEGF or PlGF decreases from the first measurement to the next measurement.

10 In a related aspect, the invention provides a kit for the diagnosis of pre-eclampsia or eclampsia in a subject comprising a component useful for detecting a sFlt-1, VEGF, or PlGF polypeptide, or any combination thereof. In one embodiment, the component is an assay selected from the group consisting of an immunological assay, an enzymatic assay, and a colorimetric assay. In
15 other embodiments of the above aspects, the kit diagnoses a propensity to develop pre-eclampsia or eclampsia in a pregnant or a non-pregnant subject. In preferred embodiments of the above aspects, the kit detects VEGF, sFlt-1, or PlGF. In other preferred embodiments of the above aspects, when the kit detects VEGF then sFlt-1 or PlGF is also detected. In additional preferred
20 embodiments, the kit is used to detect VEGF, sFlt-1 and PlGF and to determine the PAAI of the sample.

In another aspect, the invention provides a diagnostic kit for the diagnosis of pre-eclampsia or eclampsia in a subject that includes a nucleic acid sequence, or fragment thereof, selected from the group consisting of sFlt-1,
25 VEGF, and PlGF nucleic acid molecule, or a sequence complementary thereto, or any combination thereof. In a preferred embodiment, the kit comprises at least two probes for the detection of an sFlt-1, VEGF, or PlGF nucleic acid molecule.

The invention also provides a kit for the diagnosis of pre-eclampsia or
30 eclampsia in a subject that includes a PlGF binding agent for detecting free PlGF in a urine sample and instructions for its used for the diagnosis of pre-

eclampsia or eclampsia, or a propensity to develop pre-eclampsia or eclampsia in a subject. The kit can also include a component useful for an assay selected from the following: an immunological assay (e.g., an ELISA) an enzymatic assay or a colorimetric assay. Desirably, the kit includes any of the

5 components needed to perform any of the diagnostic methods described above. For example, the kit desirably includes a membrane, where the PlGF binding agent or the agent that binds the PlGF binding agent is immobilized on the membrane. The membrane can be supported on a dipstick structure where the sample is deposited on the membrane by placing the dipstick structure into the

10 sample or the membrane can be supported in a lateral flow cassette where the sample is deposited on the membrane through an opening in the cassette.

In preferred embodiments of any of the diagnostic kits described above, the diagnostic kits include a label or instructions for the intended use of the kit components and a reference sample or purified proteins to be used to establish

15 a standard curve. In one embodiment, the diagnostic kit is labeled or includes instructions for use in the diagnosis of pre-eclampsia or eclampsia, or a propensity to develop pre-eclampsia or eclampsia in a subject. In another embodiment, the diagnostic kit is labeled or includes instructions for use in the diagnosis of a cardiovascular condition or a propensity to develop a

20 cardiovascular condition. In yet another embodiment, the diagnostic kit is labeled or includes instructions for use in therapeutic monitoring or therapeutic dosage determination. In a preferred embodiment, the diagnostic kit includes a label or instructions for the use of the kit to determine the PAAI of the subject sample and to compare the PAAI to a reference sample value. It will be

25 understood that the reference sample values will depend on the intended use of the kit. For example, the sample can be compared to a normal PAAI reference value or a normal PlGF value, wherein an increase in the PAAI or a decrease in the PlGF value is indicative of pre-eclampsia or eclampsia, or a propensity to develop pre-eclampsia or eclampsia. In another example, a kit used for

30 therapeutic monitoring can have a reference PAAI value or PlGF value that is

indicative of pre-eclampsia or eclampsia, wherein a decrease in the PAAI value or an increase in the PlGF value of the subject sample relative to the reference sample can be used to indicate therapeutic efficacy or effective dosages of therapeutic compounds.

- 5 Any of the methods and kits described herein can be used to diagnose pre-eclampsia or eclampsia or to predict a subsequent pre-eclampsia in a previously pregnant woman or a woman with a history of pre-eclampsia.

Any of the diagnostic methods described herein can also be used to monitor pre-eclampsia or eclampsia in the subject. In preferred embodiments, 10 the diagnostic methods are used to monitor the subject during therapy or to determine effective therapeutic dosages. In one embodiment, a decrease in the level of sFlt-1 polypeptide or nucleic acid measured during or after administering therapy relative to the value before therapy indicates an improvement in the pre-eclampsia or eclampsia. In a preferred embodiment, a 15 level of sFlt-1 polypeptide less than 2 ng/ml indicates an improvement in the pre-eclampsia or eclampsia. In another embodiment, a therapeutic compound is administered in a dose such that the level of sFlt-1 polypeptide is less than 2ng/ml. In another embodiment, an increase in the level of VEGF or PlGF polypeptide or nucleic acid measured during or after administering therapy 20 relative to the value before therapy indicates an improvement in the pre-eclampsia or eclampsia. In yet another embodiment, a decrease in the PAAI value of a subject indicates an improvement in the pre-eclampsia or eclampsia. In preferred embodiments, the PAAI is less than 20, more preferably less than 10. A decrease in the PAAI can also indicate an effective dosage of a 25 therapeutic compound. In one example, a therapeutic compound is administered in a dose such that the PAAI is less than 20. In another example, a therapeutic compound is administered in a dose such that the PAAI is less than 10. In preferred embodiments, the measuring of the levels of sFlt-1, PlGF,

or VEGF is done on two or more occasions and a change in the levels between measurements is used to monitor therapy or to determine therapeutic dosages of a compound.

The diagnostic methods described above that include the measurement of free PlGF in a urine sample can be used to monitor the subject during therapy or to determine effective therapeutic dosages. For example, a urine test for PlGF levels as described above can be used on a regular basis (e.g., monthly, weekly, every other day, daily, or hourly) for the duration of the therapy to monitor the subject. In one embodiment, the therapeutic compound is administered in a dose such that the PlGF concentration is greater than 200 pg/ml, 300 pg/ml, 400 pg/ml, 500pg/ml, 600pg/ml, 700 pg/ml or 800 pg/ml. For monitoring assays using PlGF, the reference sample will be a concentration of PlGF indicative of pre-eclampsia (less than 400 pg/ml) and an increase in the PlGF concentration as compared to the reference sample will indicate an effective dosage of a therapeutic compound.

In a related aspect, the invention features a device for diagnosing a subject as having or having a propensity to develop pre-eclampsia or eclampsia that includes a component for comparing the levels of at least one of sFlt-1, VEGF, and PlGF polypeptides in a sample from a subject relative to a reference sample, wherein an alteration in the levels of at least one of sFlt-1, VEGF, and PlGF diagnoses pre-eclampsia or eclampsia or a propensity to develop pre-eclampsia or eclampsia in the subject. In a preferred embodiment the device includes a component for using a metric to compare the levels as at least two of sFlt-1, VEGF, and PlGF polypeptides.

In a related aspect, the invention features a device for diagnosing a subject as having or having a propensity to develop pre-eclampsia or eclampsia that includes a component for comparing the levels of at least one of sFlt-1, VEGF, and PlGF nucleic acid molecules in a sample from a subject relative to a reference sample, wherein an alteration in the levels of at least one of sFlt-1, VEGF, and PlGF diagnoses pre-eclampsia or eclampsia or a propensity to

develop pre-eclampsia or eclampsia in the subject. In a preferred embodiment the device includes a component for using a metric to compare the levels as at least two of sFlt-1, VEGF, and PlGF nucleic acid molecules.

5 In another aspect, the invention provides a method of identifying a compound that ameliorates pre-eclampsia or eclampsia by contacting a cell that expresses a sFlt-1, VEGF, or PlGF nucleic acid molecule with a candidate compound, and comparing the level of expression of the nucleic acid molecule in the cell contacted by the candidate compound with the level of expression in a control cell not contacted by the candidate compound, where an alteration in expression of the sFlt-1, VEGF, or PlGF
10 nucleic acid molecule identifies the candidate compound as a compound that ameliorates pre-eclampsia or eclampsia.

In one embodiment, the alteration is a decrease in the level of sFlt-1. In other embodiments, the alteration is an increase in the level of VEGF or PlGF. In other
15 embodiments, the alteration is in transcription or in translation. In another embodiment, when the method identifies a candidate compound that increases the expression of VEGF, the candidate compound also increases the expression of PlGF or decreases the expression of sFlt-1.

In another aspect, the invention provides a pharmaceutical composition including a VEGF or PlGF polypeptide or portion thereof, formulated in a
20 pharmaceutically acceptable carrier.

In a related aspect, the invention provides a pharmaceutical composition comprising a PlGF nucleic acid molecule, or portion thereof, formulated in a pharmaceutically acceptable carrier. In one embodiment, the composition further contains a VEGF nucleic acid molecule, or portion thereof.

25 In another aspect, the invention provides a composition comprising a purified antibody or antigen-binding fragment thereof that specifically binds sFlt-1. In one preferred embodiment, the antibody prevents binding of a growth factor to sFlt-1. In another embodiment, the antibody is a monoclonal antibody. In other preferred embodiments, the antibody or antigen-binding fragment thereof is a human or
30 humanized antibody. In other embodiments, the antibody lacks an Fc portion. In still

other embodiments, the antibody is an F(ab')₂, an Fab, or an Fv structure. In other embodiments, the antibody or antigen-binding fragment thereof is present in a pharmaceutically acceptable carrier.

In another aspect, the invention provides a method of identifying a compound
5 that ameliorates pre-eclampsia or eclampsia that involves contacting a cell that expresses an sFlt-1, VEGF, or PlGF polypeptide with a candidate compound, and comparing the level of expression of the polypeptide in the cell contacted by the candidate compound with the level of polypeptide expression in a control cell not contacted by the candidate compound, where an alteration in the expression of the
10 sFlt-1, VEGF, or PlGF polypeptide identifies the candidate compound as a compound that ameliorates pre-eclampsia or eclampsia. In one embodiment, the alteration in expression is assayed using an immunological assay, an enzymatic assay, or an immunoassay. In one embodiment, the alteration in expression is a decrease in the level of sFlt-1. In another embodiment, the alteration in expression is an increase in
15 the level of VEGF or PlGF.

In another aspect, the invention provides a method of identifying a compound that ameliorates pre-eclampsia or eclampsia that involves contacting a cell that expresses an sFlt-1, VEGF, or PlGF polypeptide with a candidate compound, and comparing the biological activity of the polypeptide in the cell contacted by the
20 candidate compound with the level of biological activity in a control cell not contacted by the candidate compound, where an increase in the biological activity of the sFlt-1, VEGF, or PlGF polypeptide identifies the candidate compound as a compound that ameliorates pre-eclampsia or eclampsia. In one embodiment, the increase in biological activity is assayed using an immunological assay, an enzymatic
25 assay, or an immunoassay. In one embodiment, the alteration in expression is a decrease in the activity of sFlt-1. In another embodiment, the alteration in expression is an increase in the activity of VEGF or PlGF.

In another aspect, the invention provides a method of identifying a compound that ameliorates pre-eclampsia or eclampsia that involves detecting binding between
30 an sFlt-1 polypeptide and a growth factor in the presence of a candidate compound, where a decrease in the binding, relative to binding between the sFlt-1 polypeptide and the growth factor in the absence of the candidate compound identifies the

candidate compound as a compound that ameliorates pre-eclampsia or eclampsia. In one embodiment, the growth factor is VEGF. In another embodiment, the growth factor is PlGF.

In another aspect, the invention provides a method of identifying a polypeptide, or fragment thereof, that prevents binding between an sFlt-1 polypeptide and a growth factor. The method involves detecting binding between an sFlt-1 polypeptide and a growth factor in the presence of the candidate polypeptide, where a decrease in the binding, relative to binding between the sFlt-1 polypeptide and the growth factor in the absence of the candidate polypeptide identifies the candidate polypeptide as a polypeptide that prevents binding between an sFlt-1 polypeptide and a growth factor. In one embodiment, the growth factor is VEGF. In another embodiment, the growth factor is PlGF.

In another aspect, the invention provides a method of identifying a compound that ameliorates pre-eclampsia or eclampsia, that involves detecting binding of an sFlt-1 polypeptide and a candidate compound, where a compound that binds the sFlt-1 polypeptide ameliorates pre-eclampsia or eclampsia.

In a related aspect, the invention provides a compound identified according to the previous aspect, where the compound is a polypeptide that specifically binds an sFlt-1 polypeptide and prevents the sFlt-1 polypeptide from binding VEGF or PlGF. In one preferred embodiment, the polypeptide is an antibody. In another preferred embodiment, the polypeptide is a fragment of sFlt-1, VEGF, or PlGF.

In preferred embodiments of the above aspects, the compound that ameliorates pre-eclampsia or eclampsia decreases the expression levels or biological activity of sFlt-1. In preferred embodiments of the above aspects, the compound that ameliorates pre-eclampsia or eclampsia increases the expression levels or biological activity of VEGF or PlGF.

In yet another aspect, the invention features a method of diagnosing a subject as having or having a propensity to develop a cardiovascular condition. This method involves measuring the level of sFlt-1 polypeptide in a sample from the subject and comparing it to a reference sample, wherein an alteration in the subject sample level diagnoses a cardiovascular condition or a propensity to develop a cardiovascular condition in the subject. In preferred embodiments, the measuring is done using an immunological assay such as an ELISA.

In a related aspect, the invention features a method of diagnosing a subject as having or having a propensity to develop a cardiovascular condition. This method includes measuring the level of sFlt-1 nucleic acid molecule in a sample from the subject and comparing it to a reference sample, wherein an alteration in the level
5 diagnoses a cardiovascular condition or a propensity to develop a cardiovascular condition in the subject.

In preferred embodiments of the above aspects, the subject is a female that is or has been pregnant. In additional preferred embodiments, the female subject has a history of pre-eclampsia or eclampsia. In additional preferred embodiments, the
10 reference sample is taken from a female that does not have a history of pre-eclampsia or eclampsia.

In a related aspect, the invention features a method of diagnosing a subject as having or having a propensity to develop a cardiovascular condition. This method includes determining the nucleic acid sequence of a sFlt-1, VEGF, or PlGF gene in a
15 sample from the subject and comparing it to a reference sequence, wherein an alteration in the subject's nucleic acid sequence that is an alteration that changes the expression level or biological activity of the gene product in the subject diagnoses a cardiovascular condition or a propensity to develop a cardiovascular condition in the subject.

In preferred embodiments of the above aspects, the sample is a cell, a tissue, or a bodily fluid in which sFlt-1 is normally detectable. Preferred samples include urine, amniotic fluid, serum, plasma, cerebrospinal fluid, and placental cells or tissue. In preferred embodiments of the above aspects, the cardiovascular condition is selected from the group consisting of atherosclerosis, primary myocardial infarction,
20 secondary myocardial infarction, angina pectoris, congestive heart failure, sudden cardiac death, cerebral infarction, restenosis, syncope, ischemia, reperfusion injury, vascular occlusion, carotid obstructive disease, and transient ischemic attack.

For the purpose of the present invention, the following abbreviations and terms are defined below.

30 By "alteration" is meant a change (increase or decrease) in the expression levels of a gene or polypeptide as detected by standard art known methods such as those described above. As used herein, an alteration includes a 10% change in

expression levels, preferably a 25% change, more preferably a 40% change, and most preferably a 50% or greater change in expression levels. "Alteration" can also indicate a change (increase or decrease) in the biological activity of any of the polypeptides of the invention (e.g., sFlt-1, VEGF, or PlGF). Examples of biological activity for PlGF or VEGF include binding to receptors as measured by immunoassays, ligand binding assays or Scatchard plot analysis, and induction of cell proliferation or migration as measured by BrdU labeling, cell counting experiments, or quantitative assays for DNA synthesis such as ³H-thymidine incorporation. Examples of biological activity for sFlt-1 include binding to PlGF and VEGF as measured by immunoassays, ligand binding assays, or Scatchard plot analysis. Additional examples of assays for biological activity for each of the polypeptides are described herein. As used herein, an alteration includes a 10% change in biological activity, preferably a 25% change, more preferably a 40% change, and most preferably a 50% or greater change in biological activity.

By "antisense nucleobase oligomer" is meant a nucleobase oligomer, regardless of length, that is complementary to the coding strand or mRNA of an sFlt-1 gene. By a "nucleobase oligomer" is meant a compound that includes a chain of at least eight nucleobases, preferably at least twelve, and most preferably at least sixteen bases, joined together by linkage groups. Included in this definition are natural and non-natural oligonucleotides, both modified and unmodified, as well as oligonucleotide mimetics such as Protein Nucleic Acids, locked nucleic acids, and arabinonucleic acids. Numerous nucleobases and linkage groups may be employed in the nucleobase oligomers of the invention, including those described in U.S. Patent Application Nos. 20030114412 and 20030114407, incorporated herein by reference. The nucleobase oligomer can also be targeted to the translational start and stop sites. Preferably the antisense nucleobase oligomer comprises from about 8 to 30 nucleotides. The antisense nucleobase oligomer can also contain at least 40, 60, 85, 120, or more consecutive nucleotides that are complementary to sFlt-1 mRNA or DNA, and may be as long as the full-length mRNA or gene.

By "body mass index" is meant a number, derived by using height and weight measurements, that gives a general indication of whether or not weight falls within a

healthy range. The formula generally used to determine the body mass index is a person's weight in kilograms divided by a person's height in meters squared or weight (kg)/ (height (m))².

By "cardiovascular condition" is meant an event or disorder of the cardiovascular system. Non-limiting examples of cardiovascular conditions include atherosclerosis, primary myocardial infarction, secondary myocardial infarction, angina pectoris (including both stable and unstable angina), congestive heart failure, sudden cardiac death, cerebral infarction, restenosis, syncope, ischemia, reperfusion injury, vascular occlusion, carotid obstructive disease, transient ischemic attack, and the like.

By "compound" is meant any small molecule chemical compound, antibody, nucleic acid molecule, or polypeptide, or fragments thereof.

By "chimeric antibody" is meant a polypeptide comprising at least the antigen-binding portion of an antibody molecule linked to at least part of another protein (typically an immunoglobulin constant domain).

By "double-stranded RNA (dsRNA)" is meant a ribonucleic acid molecule comprised of both a sense and an anti-sense strand. dsRNAs are typically used to mediate RNA interference.

By "expression" is meant the detection of a gene or polypeptide by standard art known methods. For example, polypeptide expression is often detected by western blotting, DNA expression is often detected by Southern blotting or polymerase chain reaction (PCR), and RNA expression is often detected by northern blotting, PCR, or RNase protection assays.

By "fragment" is meant a portion of a polypeptide or nucleic acid molecule. This portion contains, preferably, at least 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, or 90% of the entire length of the reference nucleic acid molecule or polypeptide. A fragment may contain 10, 20, 30, 40, 50, 60, 70, 80, 90, or 100, 200, 300, 400, 500, 600, 700, 800, 900, or 1000 nucleotides or amino acids.

By "gestational age" is meant a reference to the age of the fetus, counting from the first day of the mother's last menstrual period usually referred to in weeks.

By a "history of pre-eclampsia or eclampsia" is meant a previous diagnosis of pre-eclampsia or eclampsia or pregnancy induced hypertension in the subject themselves or in a related family member.

By “homologous” is meant any gene or protein sequence that bears at least 30% homology, more preferably 40%, 50%, 60%, 70%, 80%, and most preferably 90% or more homology to a known gene or protein sequence over the length of the comparison sequence. A “homologous” protein can also have at least one biological activity of the comparison protein. For polypeptides, the length of comparison sequences will generally be at least 16 amino acids, preferably at least 20 amino acids, more preferably at least 25 amino acids, and most preferably 35 amino acids or more. For nucleic acids, the length of comparison sequences will generally be at least 50 nucleotides, preferably at least 60 nucleotides, more preferably at least 75 nucleotides, and most preferably at least 110 nucleotides. “Homology” can also refer to a substantial similarity between an epitope used to generate antibodies and the protein or fragment thereof to which the antibodies are directed. In this case, homology refers to a similarity sufficient to elicit the production of antibodies that can specifically recognize the protein at issue.

By “humanized antibody” is meant an immunoglobulin amino acid sequence variant or fragment thereof that is capable of binding to a predetermined antigen. Ordinarily, the antibody will contain both the light chain as well as at least the variable domain of a heavy chain. The antibody also may include the CH1, hinge, CH2, CH3, or CH4 regions of the heavy chain. The humanized antibody comprises a framework region (FR) having substantially the amino acid sequence of a human immunoglobulin and a complementarity determining region (CDR) having substantially the amino acid sequence of a non-human immunoglobulin (the “import” sequences).

Generally, a humanized antibody has one or more amino acid residues introduced into it from a source that is non-human. In general, the humanized antibody will comprise substantially all of at least one, and typically two, variable domains (Fab, Fab', F(ab')₂, Fabc, Fv) in which all or substantially all of the CDR regions correspond to those of a non-human immunoglobulin and all or substantially all of the FR regions are those of a human immunoglobulin consensus sequence. The humanized antibody optimally will comprise at least a portion of an immunoglobulin constant region (Fc), typically that of a human immunoglobulin. By “complementarity determining region (CDR)” is meant the three hypervariable sequences in the variable regions within each of the immunoglobulin light and heavy

chains. By “framework region (FR)” is meant the sequences of amino acids located on either side of the three hypervariable sequences (CDR) of the immunoglobulin light and heavy chains.

The FR and CDR regions of the humanized antibody need not correspond precisely to the parental sequences, e.g., the import CDR or the consensus FR may be mutagenized by substitution, insertion or deletion of at least one residue so that the CDR or FR residue at that site does not correspond to either the consensus or the import antibody. Such mutations, however, will not be extensive. Usually, at least 75%, preferably 90%, and most preferably at least 95% of the humanized antibody residues will correspond to those of the parental FR and CDR sequences.

By “hybridize” is meant pair to form a double-stranded molecule between complementary polynucleotide sequences, or portions thereof, under various conditions of stringency. (See, e.g., Wahl and Berger (1987) *Methods Enzymol.* 152:399; Kimmel, *Methods Enzymol.* 152:507, 1987.) For example, stringent salt concentration will ordinarily be less than about 750 mM NaCl and 75 mM trisodium citrate, preferably less than about 500 mM NaCl and 50 mM trisodium citrate, and most preferably less than about 250 mM NaCl and 25 mM trisodium citrate. Low stringency hybridization can be obtained in the absence of organic solvent, e.g., formamide, while high stringency hybridization can be obtained in the presence of at least about 35% formamide, and most preferably at least about 50% formamide. Stringent temperature conditions will ordinarily include temperatures of at least about 30°C, more preferably of at least about 37°C, and most preferably of at least about 42°C. Varying additional parameters, such as hybridization time, the concentration of detergent, e.g., sodium dodecyl sulfate (SDS), and the inclusion or exclusion of carrier DNA, are well known to those skilled in the art. Various levels of stringency are accomplished by combining these various conditions as needed. In a preferred embodiment, hybridization will occur at 30°C in 750 mM NaCl, 75 mM trisodium citrate, and 1% SDS. In a more preferred embodiment, hybridization will occur at 37°C in 500 mM NaCl, 50 mM trisodium citrate, 1% SDS, 35% formamide, and 100 µg/ml denatured salmon sperm DNA (ssDNA). In a most preferred embodiment, hybridization will occur at 42°C in 250 mM NaCl, 25 mM trisodium citrate, 1% SDS, 50% formamide, and 200 µg/ml ssDNA. Useful variations on these conditions will be readily apparent to those skilled in the art.

For most applications, washing steps that follow hybridization will also vary in stringency. Wash stringency conditions can be defined by salt concentration and by temperature. As above, wash stringency can be increased by decreasing salt concentration or by increasing temperature. For example, stringent salt concentration for the wash steps will preferably be less than about 30 mM NaCl and 3 mM trisodium citrate, and most preferably less than about 15 mM NaCl and 1.5 mM trisodium citrate. Stringent temperature conditions for the wash steps will ordinarily include a temperature of at least about 25°C, more preferably of at least about 42°C, and most preferably of at least about 68°C. In a preferred embodiment, wash steps will occur at 25°C in 30 mM NaCl, 3 mM trisodium citrate, and 0.1% SDS. In a more preferred embodiment, wash steps will occur at 42°C in 15 mM NaCl, 1.5 mM trisodium citrate, and 0.1% SDS. In a most preferred embodiment, wash steps will occur at 68°C in 15 mM NaCl, 1.5 mM trisodium citrate, and 0.1% SDS. Additional variations on these conditions will be readily apparent to those skilled in the art.

Hybridization techniques are well known to those skilled in the art and are described, for example, in Benton and Davis (*Science* 196:180, 1977); Grunstein and Hogness (*Proc. Natl. Acad. Sci., USA* 72:3961, 1975); Ausubel et al. (*Current Protocols in Molecular Biology*, Wiley Interscience, New York, 2001); Berger and Kimmel (*Guide to Molecular Cloning Techniques*, 1987, Academic Press, New York); and Sambrook et al., *Molecular Cloning: A Laboratory Manual*, Cold Spring Harbor Laboratory Press, New York.

By “intrauterine growth retardation (IUGR)” is meant a syndrome resulting in a birth weight which is less than 10 percent of the predicted fetal weight for the gestational age of the fetus. The current World Health Organization criterion for low birth weight is a weight less than 2,500 gm (5 lbs. 8 oz.) or below the 10th percentile for gestational age according to U.S. tables of birth weight for gestational age by race, parity, and infant sex (Zhang and Bowes, *Obstet. Gynecol.* 86:200-208, 1995). These low birth weight babies are also referred to as “small for gestational age (SGA)”. Pre-eclampsia is a condition known to be associated with IUGR or SGA.

By “metric” is meant a measure. A metric may be used, for example, to compare the levels of a polypeptide or nucleic acid molecule of interest. Exemplary metrics include, but are not limited to, mathematical formulas or algorithms, such as ratios. The metric to be used is that which best discriminates between levels of sFlt-1,

VEGF, or PlGF in a subject having pre-eclampsia or eclampsia and a normal control subject. Depending on the metric that is used, the diagnostic indicator of eclampsia or pre-eclampsia may be significantly above or below a reference value (e.g., from a control subject not having pre-eclampsia or eclampsia).

5 sFlt-1 level is measured by measuring the amount of free, bound (i.e., bound to growth factor), or total sFlt-1 (bound + free). VEGF or PlGF levels are determined by measuring the amount of free PlGF or free VEGF (i.e., not bound to sFlt-1). One exemplary metric is $[sFlt-1/(VEGF + PlGF)]$, also referred to as the pre-eclampsia anti-angiogenic index (PAAI).

10 By “operably linked” is meant that a gene and a regulatory sequence(s) are connected in such a way as to permit gene expression when the appropriate molecules (e.g., transcriptional activator proteins) are bound to the regulatory sequence(s).

 By “pharmaceutically acceptable carrier” is meant a carrier that is physiologically acceptable to the treated mammal while retaining the therapeutic
15 properties of the compound with which it is administered. One exemplary pharmaceutically acceptable carrier substance is physiological saline. Other physiologically acceptable carriers and their formulations are known to one skilled in the art and described, for example, in Remington’s Pharmaceutical Sciences, (20th edition), ed. A. Gennaro, 2000, Lippincott, Williams & Wilkins, Philadelphia, PA.

20 By “placental growth factor (PlGF)” is meant a mammalian growth factor that is homologous to the protein defined by GenBank accession number P49763 and that has PlGF biological activity. PlGF is a glycosylated homodimer belonging to the VEGF family and can be found in two distinct isoforms through alternative splicing mechanisms. PlGF is expressed by cyto- and syncytiotrophoblasts in the placenta and
25 PlGF biological activities include induction of proliferation, migration, and activation of endothelial cells, particularly trophoblast cells.

 By “polymorphism” is meant a genetic variation, mutation, deletion or addition in an sFlt-1, PlGF, or VEGF nucleic acid molecule that is indicative of a predisposition to develop the conditions. Such polymorphisms are known to the
30 skilled artisan and are described by Parry et al. (*Eur. J Immunogenet.* 26:321-3, 1999). A polymorphism may be present in the promoter sequence, an open reading frame, intronic sequence, or untranslated 3’ region of an sFlt-1 gene.

By “pre-eclampsia” is meant the multi-system disorder that is characterized by hypertension with proteinuria or edema, or both, glomerular dysfunction, brain edema, liver edema, or coagulation abnormalities due to pregnancy or the influence of a recent pregnancy. Pre-eclampsia generally occurs after the 20th week of gestation.

5 Pre-eclampsia is generally defined as some combination of the following symptoms: (1) a systolic blood pressure (BP) >140 mmHg and a diastolic BP >90 mmHg after 20 weeks gestation (generally measured on two occasions, 4-168 hours apart), (2) new onset proteinuria (1+ by dipstick on urinalysis, >300mg of protein in a 24-hour urine collection, or a single random urine sample having a protein/creatinine ratio >0.3),
10 and (3) resolution of hypertension and proteinuria by 12 weeks postpartum. Severe pre-eclampsia is generally defined as (1) a diastolic BP > 110 mmHg (generally measured on two occasions, 4-168 hours apart) or (2) proteinuria characterized by a measurement of 3.5 g or more protein in a 24-hour urine collection or two random urine specimens with at least 3+ protein by dipstick. In pre-eclampsia, hypertension
15 and proteinuria generally occur within seven days of each other. In severe pre-eclampsia, severe hypertension, severe proteinuria and HELLP syndrome (hemolysis, elevated liver enzymes, low platelets) or eclampsia can occur simultaneously or only one symptom at a time. Occasionally, severe pre-eclampsia can lead to the development of seizures. This severe form of the syndrome is referred to as
20 “eclampsia.” Eclampsia can also include dysfunction or damage to several organs or tissues such as the liver (e.g., hepatocellular damage, periportal necrosis) and the central nervous system (e.g., cerebral edema and cerebral hemorrhage). The etiology of the seizures is thought to be secondary to the development of cerebral edema and focal spasm of small blood vessels in the kidney.

25 By “pre-eclampsia anti-angiogenesis index (PAAI)” is meant the ratio of sFlt-1/VEGF + PlGF used as an indicator of anti-angiogenic activity. A PAAI greater than 10, more preferably greater than 20, is considered to be indicative of pre-eclampsia or risk of pre-eclampsia.

30 By “protein” or “polypeptide” or “polypeptide fragment” is meant any chain of more than two amino acids, regardless of post-translational modification (e.g., glycosylation or phosphorylation), constituting all or part of a naturally occurring polypeptide or peptide, or constituting a non-naturally occurring polypeptide or peptide.

By “reduce or inhibit” is meant the ability to cause an overall decrease preferably of 20% or greater, more preferably of 50% or greater, and most preferably of 75% or greater, in the level of protein or nucleic acid, detected by the aforementioned assays (see “expression”). In embodiments that relate to the use of antisense nucleobase oligomers or RNA interference to reduce or inhibit the levels of protein or nucleic acid, the % reduction or inhibition is determined by comparing the levels in the treated sample to the levels in a sample not treated with antisense nucleobase oligomers or dsRNA.

By “reference sample” is meant a sample taken from a subject prior to the time of the test sample, a pregnant subject not having pre-eclampsia or eclampsia, a subject that is pregnant but the sample was taken early in pregnancy (e.g., in the first or second trimester or before the detection of pre-eclampsia or eclampsia), a subject that is pregnant but does not have pre-eclampsia or eclampsia and has no history of pre-eclampsia or eclampsia, or a subject that is not pregnant. A reference sample can also be a purified polypeptide (e.g., PlGF, VEGF, or sFlt-1) at a concentration known to be a normal concentration not diagnostic of pre-eclampsia or eclampsia. For example, urinary PlGF concentrations during normal pregnancy may range from 400-800 pg/ml, whereas those with active preeclampsia may be below 200 pg/ml during mid-gestation. A level of urinary PlGF below 400 pg/ml or below 200 pg/ml is indicative of pre-eclampsia or a propensity to develop preeclampsia. A “reference sample” can also be a reference standard or level. By “reference standard or level” is meant a value or number derived from a reference sample. The reference standard or level can also be a value or number derived from a normal subject that is matched to the sample subject by at least one of the following criteria: gestational age of the fetus, maternal age, maternal blood pressure prior to pregnancy, maternal blood pressure during pregnancy, BMI of the mother, weight of the fetus, prior diagnosis of pre-eclampsia or eclampsia, and a family history of pre-eclampsia or eclampsia. A reference value can also be used which is determined based on the values of a particular polypeptide in a reference sample.

By “small interfering RNAs (siRNAs)” is meant an isolated dsRNA molecule, preferably greater than 10 nucleotides in length, more preferably greater than 15 nucleotides in length, and most preferably greater than 19 nucleotides in length that is used to identify the target gene or mRNA to be degraded. A range of 19-25

nucleotides is the most preferred size for siRNAs. siRNAs can also include short hairpin RNAs in which both strands of an siRNA duplex are included within a single RNA molecule. siRNA includes any form of dsRNA (proteolytically cleaved products of larger dsRNA, partially purified RNA, essentially pure RNA, synthetic RNA, recombinantly produced RNA) as well as altered RNA that differs from naturally occurring RNA by the addition, deletion, substitution, and/or alteration of one or more nucleotides. Such alterations can include the addition of non-nucleotide material, such as to the end(s) of the 21 to 23 nt RNA or internally (at one or more nucleotides of the RNA). In a preferred embodiment, the RNA molecules contain a 3'hydroxyl group. Nucleotides in the RNA molecules of the present invention can also comprise non-standard nucleotides, including non-naturally occurring nucleotides or deoxyribonucleotides. Collectively, all such altered RNAs are referred to as analogs of RNA. siRNAs of the present invention need only be sufficiently similar to natural RNA that it has the ability to mediate RNA interference (RNAi). As used herein, RNAi refers to the ATP-dependent targeted cleavage and degradation of a specific mRNA molecule through the introduction of small interfering RNAs or dsRNAs into a cell or an organism. As used herein "mediate RNAi" refers to the ability to distinguish or identify which RNAs are to be degraded.

By "soluble Flt-1 (sFlt-1)" (also known as sVEGF-R1) is meant the soluble form of the Flt-1 receptor, that is homologous to the protein defined by GenBank accession number U01134, and that has sFlt-1 biological activity. The biological activity of an sFlt-1 polypeptide may be assayed using any standard method, for example, by assaying sFlt-1 binding to VEGF. sFlt-1 lacks the transmembrane domain and the cytoplasmic tyrosine kinase domain of the Flt-1 receptor. sFlt-1 can bind to VEGF and PlGF with high affinity, but it cannot induce proliferation or angiogenesis and is therefore functionally different from the Flt-1 and KDR receptors. sFlt-1 was initially purified from human umbilical endothelial cells and later shown to be produced by trophoblast cells *in vivo*. As used herein, sFlt-1 includes any sFlt-1 family member or isoform. In additional embodiments, sFlt-1 can also mean degradation products or fragments that result from enzymatic cleavage of the Flt-1 receptor and that maintain sFlt-1 biological activity. In one example, specific metalloproteinases released from the placenta may cleave the extracellular domain of Flt-1 receptor to release the N-terminal portion of Flt-1 into circulation.

By “specifically binds” is meant a compound or antibody which recognizes and binds a polypeptide of the invention but that does not substantially recognize and bind other molecules in a sample, for example, a biological sample, which naturally includes a polypeptide of the invention. In one example, an antibody that specifically
5 binds sFlt-1 does not bind Flt-1.

By “subject” is meant a mammal, including, but not limited to, a human or non-human mammal, such as a bovine, equine, canine, ovine, or feline. Included in this definition are pregnant, post-partum, and non-pregnant mammals.

By “substantially identical” is meant an amino acid sequence which differs
10 only by conservative amino acid substitutions, for example, substitution of one amino acid for another of the same class (e.g., valine for glycine, arginine for lysine, etc.) or by one or more non-conservative substitutions, deletions, or insertions located at positions of the amino acid sequence which do not destroy the function of the protein. Preferably, the amino acid sequence is at least 70%, more preferably at least about
15 80%, and most preferably at least about 90% homologous to another amino acid sequence. Methods to determine identity are available in publicly available computer programs. Computer program methods to determine identity between two sequences include, but are not limited to, the GCG program package (Devereux et al., *Nucleic Acids Research* 12: 387, 1984), BLASTP, BLASTN, and FASTA (Altschul et al., *J.*
20 *Mol. Biol.* 215:403 (1990). The well-known Smith Waterman algorithm may also be used to determine identity. The BLAST program is publicly available from NCBI and other sources (*BLAST Manual*, Altschul, et al., NCBI NLM NIH, Bethesda, MD 20894; BLAST 2.0 at <http://www.ncbi.nlm.nih.gov/blast/>). These software programs match similar sequences by assigning degrees of homology to various substitutions,
25 deletions, and other modifications. Conservative substitutions typically include substitutions within the following groups: glycine, alanine; valine, isoleucine, leucine; aspartic acid, glutamic acid, asparagine, glutamine; serine, threonine; lysine, arginine; and phenylalanine, tyrosine.

By “symptoms of pre-eclampsia” is meant any of the following: (1) a systolic
30 blood pressure (BP) >140 mmHg and a diastolic BP >90 mmHg after 20 weeks gestation, (2) new onset proteinuria (1+ by dipstick on urinalysis, >300mg of protein in a 24 hour urine collection, or random urine protein/creatinine ratio >0.3), and (3) resolution of hypertension and proteinuria by 12 weeks postpartum. The symptoms of

pre-eclampsia can also include renal dysfunction and glomerular endotheliosis or hypertrophy. By “symptoms of eclampsia” is meant the development of any of the following symptoms due to pregnancy or the influence of a recent pregnancy:

seizures, coma, thrombocytopenia, liver edema, pulmonary edema, and cerebral edema.

By “therapeutic amount” is meant an amount that when administered to a patient suffering from pre-eclampsia or eclampsia is sufficient to cause a qualitative or quantitative reduction in the symptoms of pre-eclampsia or eclampsia as described herein. A “therapeutic amount” can also mean an amount that when administered to a patient suffering from pre-eclampsia or eclampsia is sufficient to cause a reduction in the expression levels of sFlt-1 or an increase in the expression levels of VEGF or PlGF as measured by the assays described herein.

By “treating” is meant administering a compound or a pharmaceutical composition for prophylactic and/or therapeutic purposes. To “treat disease” or use for “therapeutic treatment” refers to administering treatment to a subject already suffering from a disease to improve the subject’s condition. Preferably, the subject is diagnosed as suffering from pre-eclampsia or eclampsia based on identification of any of the characteristic symptoms described below or the use of the diagnostic methods described herein. To “prevent disease” refers to prophylactic treatment of a subject who is not yet ill, but who is susceptible to, or otherwise at risk of, developing a particular disease. Preferably a subject is determined to be at risk of developing pre-eclampsia or eclampsia using the diagnostic methods described herein. Thus, in the claims and embodiments, treating is the administration to a mammal either for therapeutic or prophylactic purposes.

By “trophoblast” is meant the mesectodermal cell layer covering the blastocyst that erodes the uterine mucosa and through which the embryo receives nourishment from the mother; the cells contribute to the formation of the placenta.

By “vascular endothelial growth factor (VEGF)” is meant a mammalian growth factor that is homologous to the growth factor defined in U.S. Patent Nos. 5,332,671; 5,240,848; 5,194,596; and Charnock-Jones et al. (*Biol. Reproduction*, 48: 1120-1128, 1993), and has VEGF biological activity. VEGF exists as a glycosylated homodimer and includes at least four different alternatively spliced isoforms. The biological activity of native VEGF includes the promotion of selective growth of

vascular endothelial cells or umbilical vein endothelial cells and induction of angiogenesis. As used herein, VEGF includes any VEGF family member or isoform (e.g. VEGF-A, VEGF-B, VEGF-C, VEGF-D, VEGF-E, VEGF189, VEGF165, or VEGF 121). Preferably, VEGF is the VEGF121 or VEGF165 isoform (Tischer et al.,
5 *J. Biol. Chem.* 266, 11947-11954, 1991; Neufeld et al. *Cancer Metastasis* 15:153-158, 1996), which is described in U.S. Patent Nos. 6,447,768; 5,219,739; and 5,194,596, hereby incorporated by reference. Also included are mutant forms of VEGF such as the KDR-selective VEGF and Flt-selective VEGF described in Gille et al. (*J. Biol. Chem.* 276:3222-3230, 2001). As used herein VEGF also includes any modified
10 forms of VEGF such as those described in LeCouter et al. (*Science* 299:890-893, 2003). Although human VEGF is preferred, the invention is not limited to human forms and can include other animal forms of VEGF (e.g. mouse, rat, dog, or chicken).

By "vector" is meant a DNA molecule, usually derived from a plasmid or bacteriophage, into which fragments of DNA may be inserted or cloned. A
15 recombinant vector will contain one or more unique restriction sites, and may be capable of autonomous replication in a defined host or vehicle organism such that the cloned sequence is reproducible. A vector contains a promoter operably linked to a gene or coding region such that, upon transfection into a recipient cell, an RNA is expressed.

20 Other features and advantages of the invention will be apparent from the following description of the preferred embodiments thereof, and from the claims.

Brief Description of the Drawings

Figure 1 is an autoradiogram depicting sFlt-1 mRNA and protein expression
25 levels in pre-eclampsia. Figure 1A shows mRNA expression of placental sFlt-1 from three patients with pre-eclampsia (P1, P2, P3) and three normotensive term pregnancies (N1, N2, N3) as determined by northern blot analysis. The higher band (7.5 kb) is the full length flt-1 mRNA and the lower, more abundant band (3.4 kb) is the alternatively spliced sFlt-1 mRNA. GAPDH is included as a control and the
30 arrowhead indicates 28S RNA. Patients P1 and P2 had severe pre-eclampsia, whereas patient P3 had mild pre-eclampsia. Figure 1B is a graph showing sFlt-1 levels in serum from patients with mild pre-eclampsia (mild PE), patients with severe pre-eclampsia (severe PE), and normotensive pregnant women at term (normal). sFlt-1

levels were measured by an ELISA performed for sFlt-1 using a commercially available kit (R & D Systems, Minneapolis, MN). Patients with pre-term deliveries for other reasons (pre-term) were included as additional controls to rule out gestational age specific changes. The number of patients tested is shown in parenthesis in the X axis. Samples were collected prior to delivery (t=0) and 48 hours after delivery (t=48). Figure 1C is a graph showing anti-angiogenesis index ratios (PAAI=sFlt-1/(VEGF + PlGF)) ratios at the time of delivery (t=0) as determined by ELISA for all the patients described in Figure 1B.

Figures 2A-2F are photomicrographs showing the anti-angiogenic effect of excess sFlt-1 in pre-eclampsia. Endothelial tube assays were performed using serum from four normal pregnant controls and four patients with pre-eclampsia. A representative experiment from one normal control and one patient with pre-eclampsia is shown. Figures 2A, 2B, and 2C show assays performed using serum from a normal patient, while Figures 2D, 2E, and 2F show assays performed using serum from a patient with pre-eclampsia. In Figure 2A, t=0 (10% serum from a normal pregnant woman at term); in Figure 2B, t=48 (10% serum from normal pregnant woman 48 hours after delivery); in Figure 2C, t=0 + exogenous sFlt-1 (10 ng/ml); in Figure 2D, t=0 (10% serum from pre-eclamptic woman prior to delivery); in Figure 2E, t=48 (10% serum from pre-eclamptic woman 48 hours after delivery); and in Figure 2F, t=0 + exogenous VEGF(10 ng/ml) + PlGF (10 ng/ml). The tube assay was quantitated and the mean tube length +/- SEM is shown in pixels at the bottom of each panel.

Figures 3A and 3B are graphs showing that inhibition of VEGF and PlGF induced vasodilation of renal microvessels by sFlt-1. Figure 3A shows that the increase in relaxation responses of rat renal arterioles to sFlt-1 (S), VEGF (V), PlGF (P) was measured at three different doses. V+ and P+ represent vasodilatory responses of the individual reagents in the presence of sFlt-1 at 100 ng/ml. All experiments were done in 6 different dissected rat renal microvessels and data is shown as mean +/- SEM. The * represents statistical significance with p<0.01 as compared to individual reagents alone. Figure 3B shows the increase in relaxation responses at physiological doses: VEGF 100 pg/ml (V), PlGF 500 pg/ml (P), sFlt-1 10 ng/ml (S), VEGF (100 pg/ml) + PlGF 500 pg/ml (V +P) or VEGF (100 pg/ml) + PlGF

500 pg/ml + sFlt-1 10 ng/ml (V + P + S). All experiments were done in 6 different dissected rat renal microvessels and data is shown as mean \pm SEM. The * represents statistical significance with $p < 0.05$ as compared with V+P.

Figures 4A and 4B are images showing sFlt-1 induction of glomerular endotheliosis. Figure 4A is photomicrograph showing hematoxylin and eosin (H & E) staining in a capillary occlusion in the sFlt-1 treated animals with enlarged glomeruli and swollen cytoplasm as compared to controls. "Glomerular endotheliosis" with bubbly cytoplasm is shown in the sFlt-1 treated animals on periodic acid schiff (PAS) stain. All light microscopy pictures were taken at 60X, original magnification. Figure 4B is an electron micrograph of sFlt-1 treated glomeruli that confirms cytoplasmic swelling of the endocapillary cells. The immunofluorescence (IF) for fibrin pictures were taken at 40X and the EM pictures were taken at 2400X, original magnification. All figures were reproduced at identical magnifications.

Figures 5A-5C are graphs showing sFlt-1 levels measured before and after the onset of pre-eclampsia by gestational age. Figure 5A is a graph showing the mean serum concentrations in pg/ml for normotensive controls (lighter line with open triangles), cases before pre-eclampsia (filled circles), and cases after pre-eclampsia - "endpoint" specimens - (filled squares) within 4-5 week gestational age windows prior to onset of labor. Brackets indicate standard error of the mean. Asterisks indicate significant differences with respect to control specimens within the same gestational age window after logarithmic transformation: * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$. Figure 5B is a graph showing the mean serum concentrations of sFlt1 in pg/ml for cases before and after the onset of pre-eclampsia within intervals of weeks before pre-eclampsia. PE indicates the arithmetic mean of 43 endpoint specimens (obtained on or following onset of pre-eclampsia). Mean gestational age (days) is indicated in parentheses below each time interval. The horizontal line indicates the level in the endpoint specimens. The vertical lines demarcate the period ≤ 5 weeks before pre-eclampsia. Figure 5C is a graph showing the mean serum concentrations of sFlt-1 in pg/ml by gestational age windows for normotensive controls and cases before pre-eclampsia, after excluding specimens obtained within 5 weeks of onset of pre-eclampsia. There are no significant differences.

Figures 6A-6C are graphs showing the levels of PlGF before and after pre-eclampsia by gestational age. Figure 6A is a graph showing PlGF levels in all specimens obtained before labor and delivery. Brackets indicate standard error of the mean. Asterisks indicate significant differences with respect to control specimens within the same interval after logarithmic transformation: ** $p < 0.01$, *** $p < 0.001$. Figure 6B is a graph showing the mean serum concentrations of PlGF in pg/ml for cases before and after onset of pre-eclampsia within intervals of weeks before pre-eclampsia. PE indicates the arithmetic mean of 43 endpoint specimens (obtained on or following onset of pre-eclampsia). Mean gestational age (days) is indicated in parentheses below each time interval. The horizontal line indicates the level in the endpoint specimens. The vertical lines demarcate the period ≤ 5 weeks before pre-eclampsia. Figure 6C is a graph showing the mean serum concentrations of PlGF in pg/ml by gestational age windows for normotensive controls and cases onset of pre-eclampsia.

Figure 7A and 7B are graphs showing sFlt-1 and PlGF levels by pre-eclampsia status and severity. Figure 7A is a graph showing the arithmetic mean serum concentrations of sFlt-1 (black bars) and PlGF (white bars) at 23-32 weeks of gestation in controls and cases (before onset of clinical disease) with mild pre-eclampsia, severe pre-eclampsia, pre-eclampsia with onset < 37 weeks, pre-eclampsia with a small for gestational age (SGA) infant, and pre-eclampsia with onset < 34 weeks. Numbers of specimens are recorded below each column pair. Adjustment for gestational age and body mass index resulted in minor changes with no affect on level of significance. Figure 7B is a graph showing the arithmetic mean serum concentrations of sFlt-1 (black bars) and PlGF (white bars) at 33-41 weeks of gestation in controls and cases (before onset of clinical disease) with mild pre-eclampsia, severe pre-eclampsia, pre-eclampsia with onset < 37 weeks, and pre-eclampsia with an SGA infant. Numbers of specimens are recorded below each column pair. Adjustment for gestational age and body mass index resulted in minor changes.

Figure 8 is an autoradiogram showing the expression of flt, sFlt-1, and related variants or fragments in PBMCs isolated from normal and preeclamptic patients. Protein lysates were analyzed by western blots using an antibody that recognizes the N-terminus of Flt-1 protein.

Figures 9A to 9D are graphs showing the concentration of urinary PlGF by intervals of gestational age. Figure 9A is a graph showing the mean PlGF concentrations before and after the onset of clinical pre-eclampsia according to gestational age. I bars represent standard errors. Figure 9B is a graph showing the mean PlGF expressed as pg per mg creatinine before and after the onset of clinical pre-eclampsia. I bars represent standard errors. Figure 9C is a graph showing the mean PlGF concentrations before and after the onset of clinical pre-eclampsia, using only first morning urine specimens. I bars represent standard errors. Figure 9D is a graph showing the mean PlGF concentrations before and after the onset of clinical pre-eclampsia, using only random urine specimens. I bars represent standard errors.

Figure 10 is a graph showing the mean concentrations of PlGF according to pre-eclampsia status and severity, before and after normalization for creatinine. PlGF concentrations and pg per mg creatinine are shown at 21-32 weeks of gestation in controls and in women who later had clinical pre-eclampsia (PE) according to whether they had mild pre-eclampsia, severe pre-eclampsia, pre-eclampsia with an onset at less than 37 weeks of gestation, pre-eclampsia and a small-for-gestational-age infant (SGA), or pre-eclampsia with an onset at less than 34 weeks of gestation. Specimens from women in whom pre-eclampsia developed were obtained before the onset of clinical disease. The P values given are for the comparisons with the specimens from the controls. I bars represent SEs.

Figure 11 is a graph showing a longitudinal plot of placental growth factor concentrations within individual women by gestational age.

Figures 12A and 12B are graphs showing scatter plots of urinary PlGF concentrations and ratios of sFlt-1 to PlGF in serum at 21-32 weeks by days of gestation. Values were obtained from paired urine and serum specimens obtained from 20 women before development of pre-eclampsia at less than 37 weeks of gestation and from 69 normotensive controls. Figure 12A shows urinary PlGF concentrations. Figure 12B shows serum ratios of sFlt1 to PlGF.

Figure 13 is a graph showing the mean urinary concentrations of placental growth factor (PlGF) in normotensive women with infants not born small-for-gestational-age (SGA), normotensive women with SGA infants, women with gestational hypertension, and women in whom preeclampsia developed before 37 weeks of gestation. Urinary PlGF concentrations in pg/ml and in pg per mg

creatinine are shown at 21-32 weeks of gestation in normotensive women whose infants were not born small-for-gestational age (NT-SGA), normotensive women with SGA infants (NT+SGA), women who subsequently developed gestational hypertension (GH), and women who subsequently developed preeclampsia before 37 weeks of gestation (PE<37 wks). Specimens from women in whom gestational hypertension or preeclampsia developed were obtained before the onset of clinical disease. The mean gestational age at specimen collection was similar in all groups. N indicates number of specimens. The P values given are for the comparisons with the specimens from the controls (NT-SGA). I bars represent SEs.

Detailed Description

We have discovered that sFlt-1 levels are elevated in blood serum samples taken from pre-eclamptic women. sFlt-1 binds to VEGF and PlGF with high affinity and blocks the mitogenic and angiogenic activity of these growth factors. Thus, sFlt-1 is an excellent diagnostic marker for pre-eclampsia and VEGF and PlGF may be used to treat pre-eclampsia. We have also discovered that PlGF levels in the urine can be used as a diagnostic tool to detect pre-eclampsia or eclampsia, or a predisposition thereto. The free form of PlGF has an average molecular weight of about 30 kDa and is small enough to be filtered by the kidney and released into the urine. PlGF, when complexed to sFlt-1, has a much greater molecular weight and would therefore not be released into the urine. When the levels of sFlt-1 are increased, sFlt-1 can complex to PlGF, thereby reducing the levels of free PlGF released into the urine. As a result, urine analysis for free PlGF levels can be used to diagnose pre-eclampsia or eclampsia or a patient at risk for having the same.

Furthermore, we have discovered therapeutic agents that interfere with sFlt-1 binding to purified VEGF or PlGF, or agents that increase levels of biologically active VEGF or PlGF, can be used to treat or prevent pre-eclampsia or eclampsia in a subject. Such agents include, but are not limited to, antibodies to sFlt-1, oligonucleotides for antisense or RNAi that reduce levels of sFlt-1, compounds that increase the levels of VEGF or PlGF, and small molecules that bind sFlt-1 and block the growth factor binding site. The invention also features methods for measuring

levels of growth factors; the methods can be used as diagnostic tools for early detection of pre-eclampsia or an increased risk of developing pre-eclampsia or eclampsia.

While the detailed description presented herein refers specifically to sFlt-1, VEGF, or PlGF, it will be clear to one skilled in the art that the detailed description can also apply to sFlt-1, VEGF, or PlGF family members, isoforms, and/or variants, and to growth factors shown to bind sFlt-1. The following examples are for the purposes of illustrating the invention, and should not be construed as limiting.

Example 1. Increased levels of sFlt-1 mRNA and protein in pregnant women with pre-eclampsia.

In an attempt to identify novel secreted factors playing a pathologic role in pre-eclampsia, we performed gene expression profiling of placental tissue from women with and without pre-eclampsia using Affymetrix U95A microarray chips.

We found that the gene for sFlt-1 was upregulated in women with pre-eclampsia.

In order to confirm the upregulation of sFlt-1 in pre-eclampsia, we performed Northern blots to analyze the placental sFlt-1 mRNA levels (Figure 1A) and ELISA assays to measure serum protein levels of sFlt-1 (Figure 1B) in pre-eclamptic pregnant women as compared with normotensive pregnant women. Pre-eclampsia was defined as (1) a systolic blood pressure (BP) >140 mmHg and a diastolic BP >90 mmHg after 20 weeks gestation, (2) new onset proteinuria (1+ by dipstick on urinalysis, >300mg of protein in a 24 hour urine collection, or random urine protein/creatinine ratio >0.3, and (3) resolution of hypertension and proteinuria by 12 weeks postpartum. Patients with underlying hypertension, proteinuria, or renal disease were excluded. Patients were divided into mild and severe pre-eclampsia based on the presence or absence of nephritic range proteinuria (>3g of protein on a 24 hour urine collection or urine protein/creatinine ratio greater than 3.0). The mean urine protein/creatinine ratios in the mild pre-eclampsia group were 0.94 +/- 0.2 and in the severe pre-eclampsia group were 7.8 +/- 2.1. The mean gestational ages of the various groups were as follows: normal 38.8 +/-0.2 weeks, mild pre-eclampsia 34 +/-1.2 weeks, severe pre-eclampsia 31.3 +/-0.6 weeks, and pre-term 29.5 +/- 2.0 weeks. Placental samples were obtained immediately after delivery. Four random samples

were taken from each placenta, placed in RNAlater stabilization solution (Ambion, Austin, TX) and stored at -70° C. RNA isolation was performed using Qiagen RNAeasy Maxi Kit (Qiagen, Valencia, CA).

We detected an increase in both placental sFlt-1 mRNA and maternal serum sFlt-1 protein in pre-eclamptic pregnant women as compared to normotensive pregnant women. The average serum level of sFlt-1 was almost four times higher in the severe pre-eclampsia patients as compared to normal control pregnant women. To exclude the possibility that this effect was due to the earlier gestational age of the pre-eclamptic cases, we also measured sFlt-1 levels in gestationally matched normotensive women delivering pre-maturely for other reasons (gestational ages 23-36 weeks), and we found no significant difference in this group compared with normotensive term pregnancies. The probes used for northern blots were obtained by PCR and included a 500 bp fragment in the coding region from pUC 118 human flt-1 cDNA, and a GAPDH cDNA that was used as normalization control.

In normal pregnancy there is a balance between pro- and anti-angiogenic factors secreted by the placenta that is necessary for adequate placental development. We hypothesized that in pre-eclampsia, increased production of sFlt-1 and decreased production of VEGF and PlGF shifts the balance in favor of anti-angiogenesis. To address the net anti-angiogenic activity we measured VEGF and PlGF serum levels and found that PlGF and VEGF serum levels were lower in patients with pre-eclampsia as compared to normal control patients (mean PlGF, 235.3 +/- 45.3 pg/ml versus 464 +/- 116.6 pg/ml) as has been described (Tidwell et al., *Am. J. Obstet. Gynecol.*, 184:1267-1272, 2001). When we incorporated sFlt-1, VEGF and PlGF levels into an anti-angiogenic index, or PAAI, as an indicator of net anti-angiogenic activity, we found that we could clearly separate the pre-eclamptic from the normal patients and that the PAAI seemed to correlate with severity of the pre-eclampsia (Figure 1C). This PAAI can be used as a diagnostic tool for the detection of pre-eclampsia in pregnant women.

Example 2. Serum from women with pre-eclampsia inhibits angiogenesis in an *in vitro* endothelial tube assay.

We hypothesized that excess circulating sFlt-1 in patients with pre-eclampsia causes endothelial dysfunction and leads to an anti-angiogenic state. To address this, we used an endothelial tube assay as an *in vitro* model of angiogenesis. Growth factor reduced Matrigel (7 mg/mL, Collaborative Biomedical Products, Bedford, MA) was placed in wells (100 µl/well) of a pre-chilled 48-well cell culture plate and incubated at 37° C for 25-30 minutes to allow polymerization. Human umbilical vein endothelial cells (30,000 + in 300 µl of endothelial basal medium with no serum, Clonetics, Walkersville, MD) at passages 3-5 were treated with 10% patient serum, plated onto the Matrigel coated wells, and incubated at 37° C for 12-16 hours. Tube formation was then assessed through an inverted phase contrast microscope at 4X (Nikon Corporation, Tokyo, Japan) and quantitatively analyzed (tube area and total length) using the Simple PCI imaging analysis software.

The conditions of the tube formation assay were adjusted such that normal human umbilical vein endothelial cells form tubes only in the presence of exogenous growth factors such as VEGF. Under these conditions, we found that while serum from normotensive women induced endothelial cells to form regular tube-like structures, serum from women with pre-eclampsia inhibited tube formation (Figure 2). Notably, by 48 hours post-partum this anti-angiogenic effect had disappeared suggesting that the inhibition of tubes noted with the serum from pre-eclampsia patients was probably due to a circulating factor released by the placenta. When sFlt-1 was added to normotensive serum at doses similar to those found in patients with pre-eclampsia, tube formation did not occur, mimicking the effects seen with the serum from pre-eclamptic women. When exogenous VEGF and PlGF were added to the assay using pre-eclamptic serum, tube formation was restored (Figure 2). Recombinant human VEGF, human PlGF, and human Flt-1Fc were used for these assays. These results suggested that the anti-angiogenic properties of pre-eclamptic serum were due to the antagonism of VEGF and PlGF by endogenous sFlt-1. These results also suggested that addition of purified VEGF and/or PlGF can reverse or mitigate the pre-eclamptic condition and can be used therapeutically.

Example 3. sFlt-1 inhibits VEGF and PlGF induced vasodilation of renal microvessels.

The causative role of sFlt-1 in vasoconstriction was determined using an *in vitro* microvascular reactivity experiment. Microvascular reactivity experiments were done as described previously using rat renal microvessels (Sato et al., *J. Surg. Res.*, 90:138-143, 2000). Kidney artery microvessels (70-170 μ m internal diameter) were dissected from rat kidneys using a 10x to 60x dissecting microscope (Olympus Optical, Tokyo, Japan). Microvessels were placed in an isolated microvessel chamber, cannulated with dual glass micropipettes measuring 30-60 μ m in diameter, and secured with a 10-0 nylon monofilament suture (Ethicon, Somerville, NJ). Oxygenated (95% oxygen and 5% carbon dioxide) Krebs' buffer solution warmed to 37° C was continuously circulated through the vessel chamber and a reservoir containing a total of 100 ml of the solution. The vessels were pressurized to 40 mmHg in a no-flow state using a burette manometer filled with a Krebs' buffer solution. With an inverted microscope (40x to 200x; Olympus CK2, Olympus Optical) connected to video camera, the vessel image was projected onto a black-and-white television monitor. An electronic dimension analyzer (Living System Instrumentation, Burlington, VT) was used to measure the internal lumen diameter. Measurements were recorded with a strip-chart recorder (Graphtec, Irvine, CA). Vessels were allowed to bathe in the microvessel chamber for at least 30 minutes prior to any intervention. In all experimental groups, the relaxation responses of kidney microvessels were examined after pre-contraction of the microvessels with U46619 (thromboxane agonist) to 40-60% of their baseline diameter at a distending pressure of 40 mmHg. Once the steady-state tone was reached, the responses to various reagents such as VEGF, PlGF, and sFlt-1 were examined. Recombinant rat VEGF, mouse PlGF, and mouse Flt-1Fc were used for these assays. All drugs were applied extraluminally. Measurements were made when the response had stabilized (usually 2-3 minutes after the drug was administered). One to four interventions were performed on each vessel. The vessels were washed with a Krebs' buffer solution and allowed to equilibrate in a drug-free Krebs' buffer solution for 20-30 minutes between interventions.

We found that sFlt-1 alone did not cause significant vasoconstriction, however it blocked the dose responsive increase in vasodilation induced by VEGF or PlGF (Figure 3A). Furthermore, we found that VEGF and PlGF, at physiological levels seen in pregnancy, induced significant dose dependent arteriolar relaxation, and that this effect was blocked by the addition of 10 ng/ml sFlt-1, a concentration observed in severely pre-eclamptic women (Figure 3B). This result suggested that circulating sFlt-1 in patients with pre-eclampsia may oppose vasorelaxation, thus contributing to hypertension. These results support the conclusion that sFlt-1 is responsible for many of the clinical and pathological symptoms of pre-eclampsia, including hypertension. Inhibition of sFlt-1, through the use of directed antibodies, for example, could reverse the effects of the protein in pre-eclamptic women and such sFlt-1 inhibitors could potentially be used as a therapeutic agent.

Example 4. Effects of sFlt-1 in an animal model of pre-eclampsia.

Based on the above results, we hypothesized that the addition of exogenous sFlt-1 would produce hypertension and proteinuria in an animal model. Adenovirus expressing sFlt-1 has been shown to produce sustained systemic sFlt-1 levels associated with significant anti-tumor activity (Kuo et al., *Proc. Natl. Acad. Sci. USA*, 98:4605-4610, 2001). This recombinant adenovirus encoding murine sFlt-1 was injected into the tail vein of pregnant Sprague-Dawley rats on day 8-9 of pregnancy. Adenovirus encoding murine Fc and sFlk1-Fc (fusion protein of mouse VEGF receptor 1 Flk1 ectodomain and Fc protein) in equivalent doses were used as controls. Flk1 has been shown to bind to VEGF, but not PlGF. Hence, sFlk1-Fc was chosen as a control to help discriminate between the anti-VEGF and the anti-PlGF activity of sFlt1.

Both pregnant and non-pregnant Sprague-Dawley rats were injected with 1×10^9 pfu of Ad Fc, Ad sFlt-1, or Ad sFlk1-Fc by tail vein injections. These adenoviruses have been described previously (Kuo et al., *supra*) and were generated at the Harvard Vector Core Laboratory. Pregnant rats were injected with the adenoviruses at day 8-9 of pregnancy (early second trimester) and blood pressure was measured at day 16-17 of pregnancy (early third trimester). In non-pregnant animals, BPs were measured at day 8 after injection of the adenoviruses. BPs were measured in the rats after anesthesia with pentobarbital sodium (60 mg/kg, i.p.). The carotid

artery was isolated and cannulated with a 3-Fr high-fidelity microtip catheter connected to a pressure transducer (Millar Instruments, Houston, TX). The Millar Mikro-Tip catheter was advanced into the artery to record blood pressure. Blood pressure and heart rate were recorded in by chart-strip recorder (model 56-1X 40-
5 006158, Gould Instrument Systems, Cleveland, OH) and averaged over a 10-minute period. Blood, tissue, and urine samples were then obtained before euthanasia. Urinary albumin was measured by standard dipstick and quantitated by competitive enzyme-linked immunoassay (ELISA) as has been described elsewhere (Cohen et al., *Kidney Intl.*, 45: 1673-1679, 1994). Urinary creatinine was measured by a picric acid
10 colorimetric procedure kit (Sigma, St. Louis, MO). We measured intrarterial blood pressures in the early third trimester of the pregnancy to mimic the natural pathology of pre-eclampsia. These experiments were also performed in non-pregnant female Sprague-Dawley rats to determine if the effects of sFlt-1 is direct or indirect through its effects on the placenta. Systemic levels of sFlt-1 on the day of blood pressure
15 measurement were confirmed by Western blot analysis to be in the range of 25-350 ng/mL in the various sFlt-1 treated animals on the day of BP measurements. Blood pressure and proteinuria in the different experimental groups is shown in Table 1.

Table 1. Blood Pressure and Proteinuria in Rats

	N	MAP (mmHg)	U alb:cr ratio
Fc (P)	5	75.6 ± 11.1	62 ± 21
sFlt-1 (P)	4	109.0 ± 19.3*	6923 ± 658*
sFlk-1Fc (P)	4	72.8 ± 14.7	50 ± 32
<hr/>			
Fc (NP)	5	89.3 ± 5.7	138 ± 78
sFlt-1 (NP)	6	117.9 ± 12.9*	12947 ± 2776*
sFlk-1Fc (NP)	4	137.3 ± 2.3*	2269 ± 669*

5 Pregnant (P) and nonpregnant (NP) rats were administered adenovirus expressing Fc (control), sFlt-1, or sFlk-1Fc protein. Mean arterial blood pressure (MAP = diastolic + 1/3 pulse pressure in mmHg) ± S.E.M and urine albumin:Cr ratio (mg of albumin per gram of creatinine) ± S.E.M were measured eight days later, corresponding to the early third trimester in the pregnant rats. N = the number of animals in each experimental group. The * represents statistical significance with $p < 0.01$ when compared with the control group (Fc).

Pregnant rats treated with sFlt-1 had significant hypertension and nephrotic range albuminuria compared with Fc controls. Nonpregnant rats administered sFlt1 also developed hypertension and proteinuria. Notably, the sFlk-Fc treated nonpregnant rats developed hypertension and proteinuria, whereas the sFlk-Fc treated pregnant rats did not. In pregnancy, therefore, the antagonism of VEGF alone is insufficient to produce pre-eclampsia, possibly due to the presence of high levels of PlGF. In the nonpregnant state, where PlGF is virtually absent, antagonism of VEGF alone is sufficient to disrupt the pro/anti-angiogenic balance and produce renal pathologies similar to those associated with pre-eclampsia. Various staining techniques were used to examine the renal lesion that was observed in all sFlt-1 treated rats (Figure 4). Harvested kidneys from the rats were fixed in Bouin's solution, sectioned and stained with H&E and PAS stains. For electron microscopy, renal tissue was fixed in glutaraldehyde, embedded in araldite-epon mixture, and ultrathin kidney sections (1 μ m) were cut, stained with Toluene blue and assessed using a Zeiss EM 10 at various magnifications. Immunofluorescence for fibrin deposits within the glomeruli was done using polyclonal anti-fibrin antibody (ICN,

Switzerland). Global and diffuse glomerular endotheliosis was the renal lesion universally observed in the sFlt-1 treated rats. We detected glomerular enlargement with occlusion of the capillary loops by swelling and hypertrophy of endocapillary cells. Numerous apparent protein resorption droplets were seen in the glomerular epithelial cells. No segmental glomerulosclerosis was observed. Isolated “double contours” and focal deposition of fibrin within the glomeruli were seen. This finding of fibrin deposition in the absence of significant mesangial interposition is similar to what has been described as typical of the pre-partum stage of the human disease (Kincaid-Smith, *Am. J. Kidney Dis.*, 17:144-148, 1991). Immunofluorescence for fibrin showed foci of fibrin deposition within the glomeruli of sFlt-1 treated animals but not Fc treated animals. The sFlk1 treated nonpregnant rats developed the same lesion. In fact, when sFlk1 was used at the same levels as sFlt-1, the renal damage was more severe in the non-pregnant rats, as there are fewer circulating pro-angiogenic molecules for the sFlt-1 to antagonize. These results suggested that elevated levels of sFlt-1 may be responsible for the glomerular endotheliosis associated with pre-eclampsia, but that this effect was independent of the placenta since glomerular changes were detected in nonpregnant as well as pregnant rats. These results also suggested that antagonism of both VEGF and PlGF is important in the pathology of pre-eclampsia as hypertension and proteinuria occurred in sFlk-1 treated non-pregnant mice but not in sFlk-1 treated pregnant mice where PlGF levels are high.

The animal model created herein can be used as an experimental model to test novel therapeutic compounds. Both the efficacy of potential therapeutic compounds and the pharmacology and toxicity can be studied using this animal model.

Example 5. Effects of sFlt-1 in an animal model of eclampsia.

Pregnant rats in their early second trimester of pregnancy are injected with exogenous sFlt-1. The rats are then monitored and tested during their early third trimester for the development of eclampsia. Tests used for detection of eclampsia can include MRI of the rat brains for the development of edema, EEG of the rat brain for the development of seizures, and histology of the rat brains to determine if endothelial damage has occurred along the blood-brain barrier and choroids-plexus using specific endothelial markers.

The animal model created herein can be used as an experimental model to test novel therapeutic compounds. Both the efficacy of potential therapeutic compounds and the pharmacology and toxicity can be studied using this animal model.

5 Example 6: PlGF/creatinine ratio in urine is diagnostic of pre-eclampsia.

Urine samples were obtained from 10 women at 16 weeks gestation (five normals, four mild preeclamptics, and one severe pre-eclamptic). These samples were provided by Dr. Ravi Thadhani at Massachusetts General Hospital. The average urinary free PlGF/creatinine ratios (pg PlGF per mg of creatinine) for the normal pregnant women were 78 \pm 10.7 and for the four mild pre-eclamptics were 33 \pm 5.0 and for the one severe preeclamptic patient was 17. Thus, an alteration in the ratio of PlGF to creatinine in urine is useful as a diagnostic indicator for pre-eclampsia in a patient.

15 Example 7: Urinary PlGF levels measure in control and pre-eclamptic pregnant women.

Urinary PlGF was measured in control pregnant women and pre-eclamptic women using archived urine specimens from the CPEP trial (see Example 8) in collaboration with Dr. Richard Levine at the NIH (Table 2). The table below shows significant decreases in urinary PlGF in patients who later developed pre-eclampsia during mid-pregnancy (22- 30 weeks) and late pregnancy (>30 weeks), but not in early pregnancy (<20 weeks). All urine specimens were obtained prior to clinical symptoms of pre-eclampsia.

25 Table 2. Urinary PlGF levels in pg/ml in pre-eclamptic versus control pregnant patients.

	Control (n=118)	PE (n=120)
Early pregnancy	39.80	42.28
Mid pregnancy	193.11	98.66 (p<0.0001)
Late pregnancy	107.82	62.05 (p=0.0213)

Example 8: sFlt-1 and PlGF protein levels as a diagnostic indicator of pre-eclampsia and eclampsia in women.

For this study we used archived samples from the Calcium for Pre-eclampsia Prevention trial in order to analyze the gestational patterns of circulating sFlt-1, free
5 PlGF, and free VEGF in normotensive and pre-eclamptic pregnancies in collaboration with Dr. Richard Levine at the NIH. Calcium for Pre-eclampsia Prevention, or CPEP, was a randomized, double-blind clinical trial conducted during 1992-1995 to evaluate the effects of daily supplementation with 2 grams elemental calcium or placebo on the incidence and severity of pre-eclampsia (Levine et al., *N. Engl. J. Med.* 337:69-76,
10 1997; Levine et al., *Control Clin. Trials* 17:442-469, 1996). Healthy nulliparous women with singleton pregnancies were enrolled between 13 and 21 weeks gestation at five participating U.S. medical centers and followed until 24 hours postpartum using a common protocol and identical data collection forms. At enrollment, all CPEP participants had blood pressure < 135/85 mm Hg, and none had renal
15 dysfunction or proteinuria. Gestational age was determined by ultrasound examination. Serum specimens were obtained from participants prior to enrollment in the trial (13-21 weeks), at 26-29 weeks, at 36 weeks if still pregnant, and when hypertension or proteinuria were noted. "Endpoint specimens" (active PE) were specimens obtained at or after onset of pre-eclampsia symptoms and signs, but before
20 labor and delivery as described elsewhere (Levine et al., 1996, *supra*). Archived blood samples from the CPEP trial were obtained through collaboration with Dr. Richard Levine at the NIH.

Participants

25 We selected subjects having complete outcome information, serum samples obtained at <22 weeks, and a liveborn male infant. Of 4,589 CPEP participants, we excluded 253 lost to follow-up, 21 whose pregnancy had terminated prior to 20 weeks, 13 missing maternal or perinatal outcome data, 4 without smoking history, 9 with hypertension not verified by chart review teams, and 32 others with stillbirths,
30 leaving 4,257 women with adequate information and live births. Among these 2,156 had male infants. After excluding one woman whose infant had a chromosomal

abnormality, 381 with gestational hypertension, and 43 without a baseline serum specimen, 1,731 women remained. Of these, 175 developed pre-eclampsia and 1,556 remained normotensive throughout pregnancy.

5 Since calcium supplementation had no effect on the risk and severity of pre-eclampsia and was unrelated to concentrations of pro- and anti-angiogenic molecules, cases and controls were chosen without regard to CPEP treatment. For each pre-eclampsia case one normotensive control was selected, matched for enrollment site, gestational age at collection of the first serum specimen (within one week), and freezer storage time at -70° C (within 12 months). 120 matched pairs (“cases” and
10 “controls”) were randomly chosen for analysis of all 657 serum specimens obtained before labor (Table 3, below). Mean gestational age at collection of the first serum specimen was 112.8 and 113.6 days in cases and controls, respectively; mean duration of freezer storage was 9.35 and 9.39 years.

15

TABLE 3. Characteristics of cases and controls at CPEP enrollment and of their newborn infants

	Characteristic	Cases (n=120)	Controls (n=118)

40 • race or ethnic group was self-reported.

For this study, hypertension was defined as a diastolic blood pressure of at least 90 mm Hg on two occasions 4-168 hours apart. Severe hypertension was defined as a diastolic blood pressure of at least 110 mm Hg on two occasions 4-168 hours apart, or one occasion if the woman had received anti-hypertensive therapy. Proteinuria was defined as 300 mg or more protein in a 24-hour urine collection, two random urine specimens 4-168 hours apart containing at least 1+ protein by dipstick, a single urine sample with a protein / creatinine ratio at least 0.35, or a single random urine specimen containing at least 2+ protein by dipstick. Severe proteinuria was diagnosed by a 24-hour urine collection sample containing at least 3.5 g protein or by two random urine specimens with at least 3+ protein by dipstick. Pre-eclampsia was defined as hypertension and proteinuria occurring within 7 days of each other; severe pre-eclampsia was defined as pre-eclampsia with severe hypertension, severe proteinuria, HELLP syndrome (hemolysis, elevated liver enzymes, low platelets), or eclampsia. The onset of pre-eclampsia was the time of detection of the first elevated blood pressure or proteinuria in the urine sample leading to the diagnosis of pre-eclampsia.

Small for gestational age (SGA) was defined as birth weight lower than the 10th percentile for gestational age according to US tables of birth weight for gestational age by race, parity, and infant sex (Zhang and Bowes 1995, *supra*).

Procedures

Assays were performed at the Beth Israel Deaconess Medical Center by laboratory personnel who were blinded to patients' diagnoses and other relevant clinical information. Specimens were randomly ordered for analysis. Enzyme-linked immunosorbent assays (ELISA) for human sFlt-1, free PlGF, and free VEGF were performed according to the manufacturer's instructions, using kits purchased from R&D Systems (Minneapolis, MN). Aliquots of serum samples which had been stored at -70°C, were thawed to room temperature, diluted with BSA/Tris-buffered saline, and incubated for 2 hours in a 96-well plate pre-coated with a capture antibody directed against sFlt-1, PlGF, or VEGF. The wells were then washed three times, incubated 20 minutes with a substrate solution containing hydrogen peroxide and tetramethylbenzidine, and the reaction quenched with 2N sulfuric acid. Optical

density was determined at 450 nm (wavelength correction 550 nm). All assays were performed in duplicate. Protein concentrations were calculated using a standard curve derived from known concentrations of the respective recombinant proteins. If the difference between duplicates exceeded 25%, the assay was repeated and initial results discarded. The assays had sensitivities of 5, 7, and 5 pg/ml for sFlt 1, PlGF, and VEGF, respectively, with inter- and intra-assay coefficients of variation of 7.6% and 3.3% for sFlt 1, 11.2% and 5.4% for PlGF, and 7.3% and 5.4% for VEGF.

Statistical analysis

Chi-square and t tests were used in analyses of maternal or infant characteristics to compare categorical or continuous variables, respectively. Although arithmetic mean values of concentrations are given in text and figures, statistical testing was performed after logarithmic transformation unless noted otherwise. Adjustment was performed using logistic regression on logarithmically transformed concentrations.

Results

Of the 120 cases, 80 developed mild and 40 severe pre-eclampsia, including 3 with HELLP syndrome and 3 with eclampsia. Case patients were shorter than control patients, had a higher body mass index, and higher baseline blood pressure (Table 2). In addition, larger proportions of case patients had pregnancies complicated by pre-term delivery or small-for-gestational age (SGA) infants. Case patients contributed an average of 2.9 serum specimens to the study; controls, 2.6 specimens.

We first confirmed that sFlt-1, PlGF, and VEGF were altered in patients with pre-eclampsia at the time of active disease as compared to gestationally matched controls from this CPEP study group. Specimens drawn at the time of established clinical pre-eclampsia (endpoint specimens) had dramatically increased sFlt-1 levels, decreased PlGF levels, and decreased VEGF levels compared to controls with gestational ages (4382 vs. 1643 pg/ml sFlt1, $p < 0.0001$; 137 vs. 669 pg/ml PlGF, $p < 0.0001$; and 6.41 vs. 13.86 pg/ml VEGF, $p = 0.06$) for cases and controls, respectively, in 23 gestational-age matched pairs) similar to prior published reports (Maynard et al., *J. Clin. Invest.* 111:649-658, 2003).

In order to evaluate the gestational pattern of sFlt-1, PlGF and VEGF levels, we measured circulating concentrations of sFlt-1, PlGF, and VEGF from serum specimens obtained from case patients and control patients within various gestational age windows. The gestational pattern of sFlt-1 protein for 120 pre-eclamptic and 120 control women is shown in Figure 5A. sFlt-1 levels in control patients remained constant until 33-36 weeks, when they rose by approximately 145 pg/ml per week until labor and delivery. Among case patients before clinical symptoms, sFlt-1 appeared to begin to rise at 21-24 weeks, with a steeper rise and a statistically significant difference from controls at 29-32 weeks (Figure 5A). Overall, differences between case and control patients measured before the onset of clinical symptoms were 17% ($p < 0.05$) at mid-gestation. The end-point specimens were significantly elevated as compared to specimens drawn prior to the disease. In order to evaluate the mechanisms of sFlt-1 rise prior to the onset of clinical disease, we plotted sFlt-1 concentrations on all pre-eclampsia patients by weeks prior to the onset of pre-eclampsia (Figure 5B). Mean sFlt-1 concentrations in specimens from case patients were plotted by completed weeks before onset of pre-eclampsia. Beginning at 5 weeks prior to pre-eclampsia, sFlt-1 concentrations rose substantially until 1 week prior to the onset of disease when they approached the concentrations observed in endpoint specimens. The increases in sFlt-1 at 4, 3, 2, and 1 week(s) before pre-eclampsia occurred with little change in mean gestational age and cannot be explained by late third trimester increases with advancing gestational age. From 8-6 to 5 weeks before pre-eclampsia sFlt-1 increased 962 pg/ml, while mean gestational age rose 31 days. About one-third of this increase in sFlt-1 cannot be attributed to advancing gestation. When sFlt-1 was graphed by gestational age in controls and in cases after removing specimens obtained ≤ 5 weeks before onset of pre-eclampsia, no substantial differences were observed (Figure 5C). These data suggest that the higher sFlt-1 concentration in case patients prior to onset of pre-eclampsia is due to acute rises in sFlt-1 within the 5 weeks before onset of clinical disease.

We then plotted the gestational pattern of PlGF protein in the same patient group as shown in Figure 6A. Control PlGF protein concentrations rose during the first two trimesters, peaked at 29-32 weeks, and fell during late gestation. Among case patients, prior to pre-eclampsia, PlGF protein concentrations followed a similar gestational pattern, but were significantly lower than controls from 13-16 weeks.

Overall, differences in PlGF between cases patients and controls measured before the onset of clinical symptoms were 35% ($p < 0.0001$) at mid-gestation. PlGF levels in cases prior to onset of pre-eclampsia is depicted by weeks before pre-eclampsia (Figure 6B), and by gestational age after removing specimens < 5 weeks before pre-eclampsia (Figure 6C). By 1 week prior to onset of pre-eclampsia, concentrations approached those observed after onset of pre-eclampsia (Figure 6B). Compared to controls, PlGF levels from case patients were moderately reduced remote from delivery, with more substantial reductions at 5 and 3 weeks before delivery. Concentrations from control patients remained high from 17-15 through 3 weeks before delivery, then fell dramatically. The graph showing PlGF levels excluding specimens obtained ≤ 5 weeks before pre-eclampsia indicates a smaller decrease in cases relative to controls at 29-32 weeks of gestation and none at all in specimens obtained from case patients at 33-36 weeks (Figure 6C). This suggests that the fall in PlGF concentrations in the weeks prior to the disease was responsible for the dramatically low levels of PlGF noted at the onset of disease (or end point specimens shown in Figure 6A).

VEGF concentrations throughout pregnancy were very low and similar in controls and cases before pre-eclampsia, except for a significant decrease in case patients at 37-41 weeks. Mean VEGF concentrations at 23-32 weeks in cases excluding specimens obtained 5 weeks before pre-eclampsia did not differ significantly from controls (11.6 vs. 12.8 pg/ml), whereas concentrations in cases including specimens ≤ 5 weeks before delivery did (5.1 vs. 12.8 pg/ml, $p < 0.01$). At 33-41 weeks case VEGF concentrations > 5 or ≤ 5 weeks before pre-eclampsia were higher and lower than controls, respectively (11.2 pg/ml and 8.3 vs. 9.7 pg/ml), although these differences were not significant.

Figure 7 depicts sFlt-1 and PlGF at 23-32 weeks (Figure 7A) and 33-41 weeks (Figure 7B) by pre-eclampsia status and severity. The graphs show that sFlt-1 increases and PlGF decreases before onset of pre-eclampsia were associated with disease severity, time of onset, and the presence of an SGA infant. At 23-32 weeks, sFlt-1 and PlGF in case patients with an SGA infant before onset of pre-eclampsia were significantly higher or lower, respectively, than corresponding concentrations in

control patients with an SGA infant. Moreover, in comparison to control patients who delivered pre-term, case patients with pre-term delivery had higher sFlt-1 and significantly lower PlGF.

To determine whether concentrations of sFlt-1 or PlGF prior to clinical signs of pre-eclampsia were associated with the risk of this condition, we calculated odds ratios for pre-eclampsia for each quartile of control values of sFlt-1 and PlGF, as compared to the lowest or highest quartile, respectively (Table 4). We also examined the pre-eclampsia risk of the extreme quartiles with respect to all other quartiles, as follows. For specimens obtained in the second- and early third-trimester, the lowest quartile of PlGF was associated with an increased risk of preterm (<37 weeks gestation) pre-eclampsia (OR 7.4, 95% CI 1.8 to 30.2 for 13-20 week specimens; OR 7.9, 95% CI 2.9 to 21.5 for 21-32 week specimens). A level of PlGF in the lowest quartile, however, was not a significant predictor of term (≥ 37 weeks) pre-eclampsia. For sFlt-1, associations with pre-eclampsia were observed only closer to disease onset. An sFlt-1 level in the highest quartile between 21 to 32 weeks gestation (but not earlier) predicted preterm pre-eclampsia (OR 5.1, 95 percent CI 2.0 to 13.0), and a level in the highest quartile between 33 and 41 weeks (but not earlier) predicted term pre-eclampsia (OR 6.0, 95 percent CI 2.9 to 12.5). This is consistent with Figure 5B, which shows that elevation of sFlt-1 occurs largely within 5 weeks of onset of clinical disease. The lowest quartile of VEGF was not predictive of pre-eclampsia.

Table 4. Odds Ratios (OR) for Pre-eclampsia at < 37 and ≥ 37 Weeks Prior to Clinical Signs by Quartiles of Total sFlt-1 and Free PlGF in Controls at 13-20, 21-32, and 33-41 Weeks Gestation

* Odds ratio adjusted for gestational age and body mass index (with 95% CI). OR with 95% CI >1.0 in bold type. Case specimens were obtained prior to clinical signs of pre-eclampsia.

These results demonstrate that sFlt-1 levels begin to rise dramatically about 5 weeks before the onset of pre-eclampsia symptoms. Parallel with the rise in sFlt-1, free PlGF and free VEGF levels fall, suggesting that the decrease in PlGF and VEGF may be due at least partially to antagonism by sFlt-1 and not due to a decrease in placental production of PlGF and VEGF. Three pre-eclampsia subgroups – severe pre-eclampsia, early onset of disease, and SGA infants – had higher sFlt-1 and lower PlGF concentrations at 23-32 weeks and at 33-41 weeks than controls or women with mild pre-eclampsia. We have also demonstrated a small but significant decrease in free PlGF beginning early in the second trimester among women destined to develop pre-eclampsia. These results demonstrate that a decrease in PlGF levels may be a useful predictor of early onset pre-eclampsia.

We describe here for the first time the gestational pattern of sFlt-1 in normal pregnancy, observing relatively stable levels throughout gestation followed by a steady increase beginning at 33-36 weeks. This rise corresponds to the late gestational fall in PlGF observed in normal pregnancy by others (Torry et al., *J. Soc. Gynecol. Invest.* 10:178-188, 1998; Taylor et al., *Am. J. Obstet. Gynecol.* 188:177-182, 2003) and in the results described herein. The temporal association, together with the knowledge that sFlt-1 interferes with PlGF ELISA measurement (Maynard et al., *supra*) suggests that the fall in free PlGF levels during late gestation may be due to the rise in sFlt-1 levels. During first and second trimesters, when placental growth is needed to keep pace with increasing fetal demands, PlGF concentrations are high and sFlt-1 concentrations are low, creating a relatively pro-angiogenic state. Later in gestation, when placental vascular growth may need to be tempered and halted, there is a rise in the anti-angiogenic sFlt-1 and resulting decrease in PlGF. In women with pre-eclampsia, the sFlt-1 rise begins earlier in gestation, approximately five weeks before symptom onset, at about 29-32 weeks gestation on average. Thus, in pre-eclampsia, the anti-angiogenic “brakes” may be applied too soon and too strongly, resulting in an exaggeration of a normal physiologic process which arrests placental growth. It seems clear that the pathologic placental changes that characterize pre-eclampsia occur early in gestation (10-14 weeks), well before the dramatic rise in sFlt-1. The resulting placental ischemia itself may enhance sFlt-1 production, ultimately triggering a burst in sFlt-1.

In addition to the large differences seen in the five weeks prior to the development of clinical symptoms, women destined to develop pre-eclampsia had small, but statistically significant, decreases in free PlGF as early as 13-16 weeks gestation. This fall in PlGF generally was not accompanied by a reciprocal increase in sFlt-1 levels. However, there was a tendency towards slightly higher sFlt-1 levels in cases during the first trimester though it was not statistically significant (For example at the 17-20 week window, average sFlt-1 levels in cases were 865.77 pg/ml vs. 795.25 in controls). This decrease in PlGF levels early on in gestation might reflect a smaller placental production of PlGF in pregnancies compromised by conditions such as pre-eclampsia or SGA. Importantly, in patients with pre-eclampsia complicated by SGA, we found a statistically significant increase in both sFlt-1 elevation and PlGF fall prior to the disease presentation. It is also possible that there is no change in placental production of PlGF in pre-eclamptics and that elevation of local sFlt-1 levels in the placenta may contribute to the decrease in circulating free PlGF. This is supported by the finding that placental PlGF, measured by immunohistochemistry, is not altered in pre-eclampsia (Zhou et al., *Am. J. Pathol.* 160:1405-1423, 2002).

In summary, we have shown that sFlt-1 starts rising in pre-eclampsia at least 5 weeks before the onset of clinical disease which is accompanied by decreases in circulating free PlGF and free VEGF. Decreased PlGF during the first trimester may serve as a predictor of pre-eclampsia and elevated sFlt-1 may serve as a predictor of proximity to clinical disease. This data in conjunction with the animal work described above demonstrating sFlt-1 alone induces pre-eclampsia like symptoms in rodents suggests a probable etiological role for sFlt-1 in the pathogenesis of pre-eclampsia. Our limited data on SGA infants and preterm delivery in controls, as compared to case patients, suggest that the increased alterations in protein levels observed in pre-eclamptic pregnancies with an SGA infant are more substantial than a difference due only to intrauterine growth restriction or pre-term delivery in the absence of pre-eclampsia.

30

Example 9. sFlt-1 protein and protein fragments detected in monocytes from normal and preeclamptic patients.

Peripheral blood mononuclear cells, rich in monocytes, were isolated from normal and pre-eclamptic patients and used to measure the levels of sFlt-1 and sFlt-1 fragments. Protein extracts were prepared from the PBMCs and Flt-1/sFlt-1 levels were analyzed by Western blots using an antibody that recognizes the N-terminus of Flt-1 protein (a region common to both proteins). The results of this experiment showed increased Flt-1 and sFlt-1 levels in the monocytes from pre-eclamptic patients (Figure 8). In addition several bands were detected that had a faster migration than full-length sFlt-1. These faster migrating bands may be degradation products, alternatively spliced isoforms, enzymatic cleavage products, or other forms of sFlt-1.

Example 10. sFlt-1 protein levels as a diagnostic indicator of cardiovascular conditions in women with a history of pre-eclampsia.

Women with a history of pre-eclampsia have been shown to have a propensity to develop cardiovascular conditions (see for example Kestenbaum et al., *Am. J. Kidney Dis.* 42:982-989, 2003). Given our discovery of the use of s-Flt-1 as a diagnostic indicator of pre-eclampsia or eclampsia or a predisposition to pre-eclampsia or eclampsia, a study was performed to determine if sFlt-1 could also be used as a diagnostic indicator of a propensity to develop cardiovascular conditions or events in women who have a history of pre-eclampsia. The results of this study are shown in Table 5.

We examined 29 normotensive women with a history of pre-eclampsia and 32 normotensive women with previous normal pregnancies at 18.0 ± 9.7 months postpartum in the General Clinical Research Centers at the Massachusetts Institute of Technology in collaboration with Dr. Ravi Thadhani at the Massachusetts General Hospital. Since pre-eclampsia often presents near term and other disorders can lead to preterm delivery, to prevent misclassification of pregnancy outcome, all normotensive women had delivered at term (>38 weeks). Women with current pregnancy, diabetes or a history of gestational diabetes, chronic hypertension, proteinuria or serum creatinine >1.0 mg/dL were excluded. After providing written informed consent, subjects underwent a history and physical examination and a urine pregnancy test. Blood was collected on the morning after an overnight fast for measurement of free

VEGF and sFlt-1. Samples were processed immediately, stored at -80°C for no longer than 18 months and were thawed only for the current study. Commercial assay ELISA kits were used for sFlt-1 and free VEGF (R&D systems, Minnesota USA).

The intra- and inter-assay coefficient of variance (CVs) for sFlt-1 and VEGF were 3.5 and 5.6, and 8.1 and 10.9, respectively. All samples were run in duplicate by technicians blinded to pregnancy outcome.

Univariate comparisons between the pregnancy outcome groups were performed using two-sample t tests, Wilcoxon rank sum test or Fisher exact test as appropriate. Logistic regression was used to calculate odds ratios for having had prior pre-eclampsia given levels of postpartum markers, and to adjust for potential confounding.

Table 5: Postpartum sFlt-1 data according to pregnancy outcome.

	Pre-eclampsia N = 29	Normotensive N = 32	P
Age (years)	33.7 \pm 5.8	30.7 \pm 7.1	0.08
Race (% Caucasian)	86	84	0.6
Months postpartum	18.0 \pm 10	18.0 \pm 10	1.0
Body mass index (kg/m^2)	29.2 \pm 7.8	25.0 \pm 5.8	0.02
Systolic blood pressure (mmHg)	111 \pm 10	105 \pm 8	0.01
Diastolic blood pressure (mmHg)	73 \pm 10	68 \pm 7	0.04
Mean arterial blood pressure (mmHg)*	86 \pm 10	81 \pm 7	0.01
Oral or subcutaneous contraception (%)	31	34	0.8
Fasting glucose (mg/dL)	81 \pm 7	80 \pm 6	0.5
Soluble fms-like tyrosine kinase (pg/ml)	41.6 \pm 6.7	30.4 \pm 10.2	< 0.01

Continuous variables are reported as mean \pm standard deviation or median (interquartile range) as appropriate.

These results indicate that women with a history of pre-eclampsia during pregnancies showed elevated levels of sFlt-1 for an extended period of time after the pregnancy. Given that statistical analysis has shown that women with a history of pre-eclampsia or eclampsia have a predisposition to develop cardiovascular conditions, these results provide support for the use of sFlt-1 post-partum levels as a diagnostic indicator of a cardiovascular condition or a propensity to develop a cardiovascular condition.

Example 11. Urine PlGF levels as a diagnostic indicator of pre-eclampsia.

In situations where obtaining serum measurements of VEGF, sFLT-1, and PlGF are not optimal, an alternative and less invasive screening method may be to measure these proteins in urine. While sFlt1 is too large a molecule (110 kDa) to be filtered into the urine in the absence of proteinuria, PlGF and VEGF, much smaller proteins (~30 kDa and 45 kDa respectively), are readily filtered. Unlike urinary PlGF, which is derived entirely from circulating blood, the major sources of urinary VEGF are cells of the kidney itself: glomerular podocytes and tubular cells. Thus, urinary VEGF is unlikely to reflect the circulating angiogenic state. We used archived urine samples to test the hypothesis that urinary PlGF is reduced well before the onset of hypertension and proteinuria and predicts pre-eclampsia.

Participants and Specimens

Serum and urine specimens were requested from participants of the CPEP clinical trial (see Example 8) before enrollment in the trial, at 26-29 weeks of gestation, at 36 weeks if they were still pregnant, and when hypertension or proteinuria was noted. Both first morning and 24-hour urine specimens were requested; if neither was available, a random or "spot" urine specimen was collected. 24-hour urines were requested from patients suspected of pre-eclampsia. "End-point specimens" referred to those obtained at or after the onset (defined below) of signs of pre-eclampsia, but before labor and delivery.

For the present study, we selected women with complete outcome information, serum samples obtained at less than 22 weeks of gestation, and a live-born male infant. This group had previously been selected for a study of fetal DNA and pre-eclampsia, in which fetal and maternal DNA were differentiated through the

amplification of a gene on the Y chromosome. Analysis of previous work revealed no significant differences in maternal serum sFlt1 or PLGF concentrations according to infant gender.

Since calcium supplementation had no effect on the risk or severity of pre-eclampsia (Levine et al., *supra*) or on the concentrations of angiogenic factors in serum (Levine et al., *N. Engl. J. Med.* 350:672-683, 2004) or urine, women were chosen without regard to whether they had received calcium supplementation or placebo. For each woman with pre-eclampsia, one normotensive control was selected, matched according to enrollment site, gestational age at the collection of the first serum specimen, and storage time of the samples at -70°C. A total of 120 matched pairs were randomly chosen for analysis of all serum and urine specimens obtained before labor. If a woman had more than one urine specimen obtained on the same day, we selected one specimen, preferring first morning to random urine and random to 24-hour urine. We identified 348 urine specimens from 120 pre-eclampsia cases and 318 from 118 normotensive controls. Two normotensive controls from the serum study had no eligible urine specimens and were excluded from further analyses.

We examined separately urine samples obtained at 21-32 weeks of gestation from controls and cases with onset of pre-eclampsia before term (<37 weeks) for which a serum specimen from the same woman had been collected within 3 days. There were a total of 89 urine-serum specimen pairs from 20 cases of preterm pre-eclampsia and 69 normotensive controls.

Pre-eclampsia was defined as described above. The time of onset of pre-eclampsia (the end-point) was defined as the time of the first elevated blood-pressure or urine protein measurement leading to the diagnosis of pre-eclampsia. A small-for-gestational-age infant was defined as an infant whose birth weight was below the 10th percentile according to U.S. tables of birth weight for gestational age that accounted for race, parity, and infant gender.

Procedures

Assays were performed by personnel who were unaware of pregnancy outcomes. Specimens were randomly ordered for analysis. Enzyme-linked immunosorbent assays (ELISAs) for sFlt, free PlGF, and free VEGF were performed

in duplicate, as previously described, with the use of commercial kits (R&D Systems, MN). The minimal detectable doses in the assays for sFlt1, PlGF, and VEGF were 5, 7, and 5 pg per milliliter, respectively, with inter-assay and intra-assay coefficients of variation of 7.6 and 3.3 percent, respectively, for sFlt1; 10.9 and 5.6 percent, for PlGF; and 7.3 and 5.4 percent, for VEGF. Urinary creatinine was measured using a commercially available picric acid colorimetric assay (Metra creatinine assay kit, Quidel Corp., CA).

Statistical Analysis

The chi-square test was used for comparison of categorical variables; and the t-test, for comparison of continuous variables. Although arithmetic mean concentrations are reported in the text and figures, statistical testing was conducted after logarithmic transformation, using the SAS / PROC GENMOD procedure (SAS v8.0, Cary, NC) in crude and adjusted analyses to account for subjects with varying numbers of specimens. Odds ratios were adjusted using logistic-regression analysis.

Results

Of the 120 women with pre-eclampsia, 80 had mild and 40 had severe disease. Compared with controls, women with pre-eclampsia had greater body-mass index, higher blood pressure at enrollment in the CPEP trial, and larger proportions of their current pregnancies complicated by preterm delivery or resulting in small-for-gestational-age infants. Patient and infant characteristics have been described previously and are briefly summarized in Table 3.

Differences in Urinary PlGF after Onset of Pre-eclampsia

We first ascertained that urinary levels of PlGF were altered in women after development of clinical pre-eclampsia. Among 22 pairs of women with pre-eclampsia and gestational-age matched controls, end-point specimens had lower levels of PlGF than specimens from controls (mean PLGF level, 32 vs. 234 pg/ml, $P < 0.001$; and 50 vs 227 pg per mg creatinine, $P < 0.001$).

Gestational Changes in Urinary PlGF

To evaluate gestational patterns, we performed cross-sectional analyses of urine obtained within gestational-age intervals of four to five weeks, with PlGF levels expressed as concentrations (Figure 9A) or as pg per mg creatinine (Figure 9B). The P values in Figure 9A are for the comparisons, after logarithmic transformation, with specimens from controls obtained during the same gestational-age interval and accounting for subjects with varying numbers of specimens. The differences, after logarithmic transformation, between the specimens obtained at 29-36 weeks from women who already had clinical pre-eclampsia and those obtained at 29-36 weeks from women in whom pre-eclampsia later developed were also significant ($P < 0.001$ for the comparison at 29-32 weeks, $P < 0.001$ for the comparison at 33-36 weeks, and $P = 0.003$ for the comparison at 37-42 weeks). Note that PlGF concentrations before onset of pre-eclampsia do not include endpoint specimens obtained after appearance of hypertension or proteinuria. Figure 9A also shows the mean serum concentrations of PlGF for the women who subsequently develop pre-eclampsia after excluding specimens obtained within 5 weeks before onset of pre-eclampsia (broken red line). The graph in Figure 9B shows that the differences, after logarithmic transformation, between the specimens obtained at 29-36 weeks from women who already had clinical pre-eclampsia and those obtained at 29-36 weeks from women in whom pre-eclampsia later developed were also significant ($P = 0.004$ for the comparison at 29-32 weeks, $P < 0.001$ for the comparison at 33-36 weeks, and $P = 0.02$ for the comparison at 37-42 weeks).

The PlGF levels in controls increased during the first two trimesters with a more rapid increase after 21-24 weeks, reaching a peak at 29-32 weeks, and decreasing thereafter. The levels in women who subsequently developed pre-eclampsia followed a similar pattern, but were significantly lower at 25-28, 29-32, and 33-36 weeks. When specimens obtained within 5 weeks before the onset of pre-eclampsia were excluded, the differences in the preceding gestational age intervals between the controls and women who later had pre-eclampsia were less pronounced. Among women with specimens obtained in the same gestational-age interval, those who already had clinical pre-eclampsia had significantly lower concentrations at 29-32, 33-36, and 37-42 weeks than those who developed pre-eclampsia later. Similar

gestational age patterns among controls and cases before and after onset of clinical pre-eclampsia were observed when restricting the analysis of specimens either to first morning (Figure 9C) or random (Figure 9D) urines.

5 *Relationship of Urinary PlGF to Severity of Pre-eclampsia*

Before the onset of pre-eclampsia, there were particularly large differences between the levels of urinary PlGF in controls and those in women who later had pre-eclampsia with onset before 37 weeks or who had pre-eclampsia and a small-for-gestational-age infant. Figure 10 shows PlGF concentrations and PlGF expressed as pg per mg creatinine between 21-32 weeks of gestation.

Alterations in urinary PlGF levels were also more pronounced in women who subsequently developed pre-eclampsia before term (<37 weeks of gestation) than in women who had an onset of pre-eclampsia at term (≥ 37 weeks) (at 21-32 weeks: PlGF concentration, 87 pg/ml in women with pre-eclampsia before term vs. 223 pg/ml in women with pre-eclampsia at term, $P < 0.001$; at 33-42 weeks: PlGF concentration, 22 pg/ml in women with pre-eclampsia before term vs. 118 pg/ml in women with pre-eclampsia at term, $P < 0.001$). Results were similar when using PlGF expressed as pg per mg creatinine or after adjusting PlGF concentrations for creatinine, gestational age at specimen collection, storage time, body mass index, and maternal age.

Furthermore, PlGF levels in specimens obtained before onset of pre-eclampsia from women who later had pre-eclampsia and a small-for-gestational-age infant were lower than in women who later had pre-eclampsia, but whose infants were not small-for-gestational-age (at 21-32 weeks: PlGF concentration, 62 vs. 205 pg/ml, $P = 0.002$; at 33-42 weeks: PlGF concentration, 42 vs. 123 pg/ml, $P = 0.06$).

25 *Odds Ratios for Pre-eclampsia Associated with Urinary PlGF*

To determine the risk of pre-eclampsia according to urinary PlGF in specimens obtained before the onset of clinical signs, we divided PlGF values into quartiles based on the distribution in controls and calculated adjusted odds ratios for pre-eclampsia in each quartile, as compared to the highest quartile (Table 6) or to all other quartiles (described below).

TABLE 6: Odds Ratios for Pre-eclampsia at Less Than 37 Weeks of Gestation and at 37 Weeks or More of Gestation According to Quartile* of Urinary PIGF

PIGF	No. of Control Specimens	PE < 37 wk		PE ≥ 37 wks	
		No. spec.	OR (95% C.I.)**	No. spec.	OR (95% C.I.)**
13 - 20 wks					
Q1: ≤ 29 pg/ml	25	6	0.6 (0.2 - 2.4)	19	0.9 (0.3 - 2.3)
Q2: 29 - 59 pg/ml	24	12	1.3 (0.4 - 4.3)	25	1.4 (0.6 - 3.3)

Q3: 153 – 268 pg/mg	25	0	N/A	8	0.6 (0.2 - 1.8)
Q4: > 268 pg/mg	24	0	N/A	10	1.0

- Quartiles were determined on the basis of control specimens
- Odds ratios were adjusted for gestational age at specimen collection, specimen storage time, maternal age and body mass index (with 95% Confidence Intervals). The reference category was the highest quartile: Q4.
- Specimens from cases were all obtained before onset of clinical signs of pre-eclampsia.

Among specimens obtained at 21-32 weeks of gestation the lowest quartile of PlGF was associated with a greatly increased risk of preterm pre-eclampsia and a small increased risk of pre-eclampsia at term. For preterm pre-eclampsia, after adjustment for gestational age at specimen collection, storage time, body mass index, and age, using PlGF concentration the odds ratio for the lowest quartile vs. all others was 22.5, 95% confidence interval, 7.4 - 67.8; and using pg PlGF per mg creatinine the odds ratio was 16.4, 95% confidence interval, 5.9 - 45.5. After restricting specimens to first morning urines, adjusted odds ratios were 39.5 with 95% confidence interval, 6.5 - 240.8; and 20.4 with 95% confidence interval, 4.5 - 92.3, for PlGF concentration and PlGF per mg creatinine, respectively. Using random urine specimens, adjusted odds ratios were 13.5 with 95% confidence interval, 2.3 - 79.8; and 11.1 with 95 % confidence interval, 2.0 - 61.3, respectively. For term pre-eclampsia, after adjustment for the factors noted above and using all urine specimens, odds ratios were 2.2 with 95% confidence interval, 1.2 - 4.3; and 2.1, 95% confidence interval, 1.1 - 4.1, respectively. For specimens obtained at 13 to 20 weeks of gestation, the lowest quartile of PlGF was neither associated with an increased risk of preterm, nor of term pre-eclampsia. However, the lowest quartile of PlGF was associated with an increased risk of term pre-eclampsia vs. all other quartiles in specimens obtained at 33-42 weeks of gestation: adjusted odds ratio 2.3 with 95% confidence interval, 1.2 - 4.5, for pg PlGF per mg creatinine.

When we performed the same analyses in specimens obtained at 21 – 32 weeks of gestation for women who developed pre-eclampsia complicated by a small-for-gestational-age infant, we found that the estimates were unstable (adjusted OR 405, 95% confidence interval, 27 – 5983, for pg PlGF per mg creatinine). This was because there were only 20 such women, all of whom were in the lowest (N = 19) or next lowest (N = 1) quartiles of urinary PlGF. Nevertheless, the data indicate that low urinary PlGF is associated with a substantial increase in risk for pre-eclampsia with a small-for-gestational-age infant.

10 *Gestational Changes in Urinary PlGF within Individual Women*

Figure 11 depicts longitudinally the changes in PlGF concentration within 13 patients with preterm pre-eclampsia (pre-eclampsia <37 weeks) and 13 controls with gestational-age matched specimens. All 13 women who developed pre-eclampsia before 37 weeks of gestation were selected who had at least a baseline urine, a urine obtained within 21-32 weeks of gestation, and an end-point urine, which might also serve as the 21-32 week specimen. Each case was matched to a control with the same or greater number of specimens obtained at similar gestational ages. One control had very low urinary PlGF per mg creatinine throughout pregnancy: 17, 5, and 0 pg/ml at 116, 177, and 248 days of gestation, respectively. This woman had a single episode of 1+ proteinuria and a single diastolic blood pressure of 90 mm Hg recorded 2 hours before delivery on day 266 of gestation. Patients with preterm pre-eclampsia had lower levels of PlGF usually throughout gestation, whereas controls tended to have levels which increased with advancing gestation and fell near term.

25 *Relationship of Urinary PlGF to Proximity to Pre-eclampsia*

Urinary concentrations of PlGF in specimens obtained at 21-32 weeks of gestation and within five weeks before the onset of pre-eclampsia were lower (43 pg/ml) than in specimens obtained more than five weeks before clinical disease (196 pg/ml, $P < 0.001$). In specimens obtained at 33-42 weeks of gestation concentrations were 110 pg/ml vs. 187 pg/ml, respectively ($P = 0.05$). There was little difference when PlGF was normalized for creatinine.

Figure 12A is a scatter plot of urinary PlGF concentrations at 21-32 weeks from 69 controls and 20 cases who subsequently developed pre-eclampsia before term (<37 weeks). Women who developed pre-eclampsia before term had lower urinary PlGF concentrations than normotensive controls. Concentrations were lowest (i.e., less than 150 pg/ml) in specimens obtained within five weeks before the onset of clinical disease. However, a number of control specimens also had low urinary PlGF. In order to distinguish these specimens from specimens obtained within five weeks prior to pre-eclampsia, we examined serum measurements of the ratio of sFlt1 to PlGF. The ratio accounts for both the increased sFlt1 and decreased PlGF observed before onset of pre-eclampsia. A scatter plot of the ratios of sFlt1 to PlGF concentrations in paired sera is given in Figure 12B. Ratios are elevated (>5) in all specimens obtained within five weeks before the onset of pre-eclampsia and exceed almost all control values.

15 *Urinary sFlt1 and Urinary VEGF in Pre-eclampsia*

We randomly selected 22 cases and 22 controls for analysis of urinary sFlt1 and VEGF within 21-32 weeks of gestation before onset of clinical pre-eclampsia. In 16 of 22 case specimens (73%) and 19 of 22 control specimens (86%) urinary sFlt1 was undetectable. In contrast, urinary VEGF was detected in all specimens, but was not significantly altered in cases before or after the onset of hypertension and proteinuria (before: 272 vs. 248 pg/ml in the groups of 22 randomly selected cases and controls, respectively, $P=0.56$; after: 167 vs. 103 pg/ml in 22 gestational-age matched cases and controls, respectively, $P=0.61$).

25 *Conclusions*

In this study of 120 women with pre-eclampsia and 118 normotensive controls, urinary concentrations of PlGF were significantly lower beginning at 25-28 weeks of gestation among the women who subsequently developed pre-eclampsia. Differences between the two groups became more pronounced at 29-36 weeks. We have previously shown that serum free PlGF was lower in cases than controls beginning at 13-16 weeks of gestation, becoming even lower after 25 weeks of gestation. As with serum measurements, in the current study urinary PlGF at 21-32 weeks of gestation was significantly decreased in those who developed pre-eclampsia

before 37 weeks or complicated by a small-for-gestational-age infant and within 5 weeks of the onset of clinical signs. Furthermore, among women in the lowest quartile of urinary PlGF concentrations (<118 pg/ml) at 21-32 weeks of gestation, the risk of developing pre-eclampsia before 37 weeks of gestation or complicated by a small-for-gestational-age infant was markedly elevated. The risk was high, irrespective of adjustment for urinary creatinine concentrations, and evident even in random urines. The association was, however, stronger with first morning specimens, which are likely to be more concentrated. Thus, urinary PlGF was especially useful for identifying the patients who would benefit most from early diagnosis. We have also demonstrated that a strategy of following urine measurement of PlGF with serum measurements of sFlt1 and PlGF in selected patients may minimize false positives from urine testing.

Urinary VEGF concentrations were reported recently to be modestly elevated in 37 women with severe pre-eclampsia, compared to 32 with uncomplicated pregnancy. We found non-significant elevations of urinary VEGF before and after the onset of pre-eclampsia, consistent with our hypothesis that urinary VEGF reflects primarily local renal VEGF production. Since urinary VEGF originates almost entirely from renal podocyte and tubular cells, it has not been exposed to circulating sFlt1, which is too large a molecule to filter freely through an intact glomerulus. Therefore, while reduced urinary PlGF in women with pre-eclampsia likely reflects reduced circulating free PlGF, the result of binding to excess circulating sFlt1, levels of urinary VEGF do not reflect the angiogenic imbalance in the blood.

The identification of angiogenic proteins which appear to mediate the maternal syndrome of pre-eclampsia may present specific targets for therapeutic intervention to restore the appropriate angiogenic balance (Maynard et al., *supra*). Prevention and treatment are especially needed for women with early onset pre-eclampsia or pre-eclampsia complicated by a small-for-gestational-age infant. However, such women must first be identified before the onset of clinical disease. These data demonstrate that a reliable and valid dipstick assay can be developed and used to screen all women for low urinary PlGF concentrations. As a follow-up for those women identified with low levels of urinary PlGF, serial serum measurements of sFlt1 and PlGF could then be used to identify more precisely individuals at high risk.

Example 12. Ancillary study demonstrating urinary PlGF during mid-pregnancy is a specific predictor of pre-eclampsia.

We performed an ancillary study to ascertain whether urinary PlGF at 21-32 weeks of gestation might differ between women with male or female infants and to determine if concentrations of urinary PlGF might be lower than normal in women with gestational hypertension and in women who remained normotensive during pregnancy, but delivered a small-for-gestational-age (SGA) infant. Among the 4256 women in the CPEP trial with adequate data who delivered a liveborn infant not known to have a chromosomal abnormality, we excluded 239 with term preeclampsia (≥ 37 weeks). Of the 4017 women remaining, 3303 had at least one urine specimen obtained within 21-32 weeks of gestation before onset of labor or delivery and before onset of preeclampsia or gestational hypertension. Among these women we randomly selected 120 whose pregnancy was normotensive and whose infant was not SGA, 60 with normotensive pregnancy who delivered an SGA infant, 60 with gestational hypertension, and 59 with preterm (< 37 weeks) preeclampsia. In each group we chose half the women to have delivered male infants and half, female infants, except for the group with preterm preeclampsia. In this group we selected 30 with male infants, but could find only 29 with female infants. PlGF was analyzed in all urine specimens obtained at 21-32 weeks gestation.

20

Preeclampsia, Gestational Hypertension, Small-for-Gestational-Age, and Institutional Review Board

Preeclampsia was defined as a newly elevated diastolic blood pressure of at least 90 mm Hg and proteinuria of at least 1+ (30 mg per deciliter) on dipstick testing, each on two occasions 4 to 168 hours apart. Severe preeclampsia was defined as the HELLP syndrome (hemolysis, elevated liver-enzyme levels, and a low platelet count), eclampsia, or preeclampsia with either severe hypertension (diastolic blood pressure ≥ 110 mm Hg) or severe proteinuria (urinary protein excretion ≥ 3.5 g per 24 hours or findings of $\geq 3+$ [300 mg per deciliter] on dipstick testing). Gestational hypertension was hypertension as defined above in the absence of proteinuria. Detailed definitions have been published (Levine et al., *N. Engl. J. Med.* 337:69-76 (1997) and Levine et al., *Control Clin. Trials* 17:442-469 (1996)). The time of onset of preeclampsia was defined as the time of the first elevated blood-pressure or urine protein measurement

30

leading to the diagnosis of preeclampsia. Similarly the onset of gestational hypertension was the time of the first elevated blood-pressure which led to the diagnosis. A small-for-gestational-age infant was an infant whose birth weight was below the 10th percentile according to U.S. tables of birth weight for gestational age that accounted for race, parity, and infant gender (Zhang et al., *Obstet. Gynecol.* 86:200-208 (1995)). Because the study used data and specimens that could not be linked to identifiable women, the office of Human Subjects Research of the National Institutes of Health granted it an exemption from the requirement for review and approval by the institutional review board.

Procedures

Assays were performed by personnel who were unaware of pregnancy outcomes. Specimens were randomly ordered for analysis. Enzyme-linked immunosorbent assays (ELISAs) for sFlt1, free PlGF, and free VEGF were performed in duplicate, as previously described, with the use of commercial kits (R&D Systems, MN). (Maynard et al., *supra*) The minimal detectable doses in the assays for sFlt1, PlGF, and VEGF were 5, 7, and 5 pg per milliliter, respectively, with inter-assay and intra-assay coefficients of variation of 7.6 and 3.3 percent, respectively, for sFlt1; 10.9 and 5.6 percent, for PlGF; and 7.3 and 5.4 percent, for VEGF. The ELISA kits for sFlt1, VEGF and PlGF were validated for use in urine specimens with 96%, 98% and 99% recovery from spiked urine samples, respectively. Urinary creatinine was measured using a commercially available picric acid colorimetric assay (Metra creatinine assay kit, Quidel Corp., CA).

Statistical Analysis

The chi-square test was used for comparison of categorical variables; and the t-test, for comparison of continuous variables. Although arithmetic mean concentrations are reported in the text and figures, statistical testing was conducted within each time interval individually after logarithmic transformation, using the generalized estimating equations (GEE) method (SAS / PROC GENMOD procedure, SAS v8.0, Cary, NC) in crude and adjusted analyses to account for subjects with varying numbers of specimens. Odds ratios were adjusted with the use of logistic-

regression analysis. Since matching was complete only for analyses of the earliest serum specimen in the entire study population, matching was not accounted for in the statistical analyses.

5 *Results*

 In order to test further the hypothesis that decreased urinary PlGF is specific for early onset preeclampsia, we performed a second study in which we analyzed urine specimens obtained at 21-32 weeks from women with other obstetrical conditions which may share similarities of pathogenesis. We compared women with
10 gestational hypertension and women who remained normotensive during pregnancy, but delivered an SGA infant, to normotensive women whose infant was not SGA (controls) and to women with preeclampsia before 37 weeks. The clinical characteristics of the women in this study and of their newborn infants are summarized in Table 7. The characteristics of women with preeclampsia and their
15 infants were similar to those reported for such women in the main study.

‡ Race or ethnicity was self-reported.

Compared to normotensive women whose infants were not SGA, women with gestational hypertension had greater body-mass index and infants of greater birthweight; and normotensive women with an SGA infant, lower body-mass index and infants of lower birthweight. Normotensive women with SGA infants were most likely and women with hypertensive disorders of pregnancy, least likely to have smoked during pregnancy.

Figure 13 depicts urinary PlGF at 21-32 weeks of gestation expressed as concentrations (pg/ml) and as pg per mg creatinine. PlGF levels in women who remained normotensive during pregnancy, but delivered an SGA infant, did not differ from those of normotensive controls whose infant was not born SGA. Similarly, levels in subjects with gestational hypertension did not differ from those of normotensive controls. However, levels of urinary PlGF in patients who developed preeclampsia before 37 weeks of gestation – collected on average 42 days prior to clinical disease - were much lower than controls (77 vs. 206 pg/ml, $p < 0.0001$). Within each group PlGF concentrations among women who delivered male or female infants did not differ significantly.

Conclusions

Urinary PlGF was much lower at 21-32 weeks of gestation in women who developed preeclampsia before 37 weeks than in women who developed gestational hypertension or delivered a small-for-gestational-age infant, two obstetrical conditions with similarities to preeclampsia. Thus, a low urinary PlGF concentration at this stage of pregnancy can likely distinguish preeclampsia from gestational hypertension and intrauterine growth retardation.

Example 13

Collaborative experiments with Dr. Steve Pollitt and Dr. Ute Schellenberger from Scios were performed in order to determine the efficacy of VEGF₁₂₁ therapy on pre-eclampsia in an animal model. Female rats with an average weight of 250 grams were used. All rats were injected with 2×10^9 pfu of adenoviruses expressing sFlt-1 on day 0. The goal of the therapy was to achieve an sFlt-1 concentration of approximately 10-20 ng/ml to mimic the concentrations we have found associated with human pre-eclampsia. The animals were separated into two groups. Animals

59-64 were injected with PBS and served as controls. Animals 65-70 were injected subcutaneously with VEGF₁₂₁ at a concentration of 25 µg/rat (approximately 100 µg/kg body weight) twice a day from day 3 to day 7.

Animals were sacrificed on the afternoon of day 7, approximately 4 to 5 hours after the last dose of VEGF. Blood pressure was obtained and the results are summarized in Table 7, below. Plasma, urine and renal tissue were also obtained and plasma sFlt-1 levels and free VEGF levels were measured by ELISA. These data are also summarized in Table 7.

Despite the variability in the circulating sFlt-1 levels, on average, the animals which received the VEGF₁₂₁ therapy demonstrated a fall in blood pressure and proteinuria. These results suggest the potential for VEGF₁₂₁ as an effective treatment of sFlt-1 induced hypertension and proteinuria.

Table 7. In Vivo Results of VEGF₁₂₁ therapy

Diagnostics

The present invention features diagnostic assays for the detection of pre-eclampsia, eclampsia, or the propensity to develop such conditions. Levels of VEGF, PlGF, or sFlt-1, either free or total levels, are measured in a subject sample and used
5 as an indicator of pre-eclampsia, eclampsia, or the propensity to develop such conditions.

In one embodiment, a metric is used to determine whether a relationship between levels of at least two of the proteins is indicative of pre-eclampsia or eclampsia. Standard methods may be used to measure levels of VEGF, PlGF, or sFlt-
10 1 polypeptide in any bodily fluid, including, but not limited to, urine, serum, plasma, saliva, amniotic fluid, or cerebrospinal fluid. Such methods include immunoassay, ELISA, "sandwich assays", western blotting using antibodies directed to VEGF, PlGF or sFlt-1, immunodiffusion assays, agglutination assays, fluorescent immunoassays, protein A or G immunoassays, and immunoelectrophoresis assays and quantitative
15 enzyme immunoassay techniques such as those described in Ong et al. (*Obstet. Gynecol.* 98:608-611, 2001) and Su et al. (*Obstet. Gynecol.*, 97:898-904, 2001). ELISA assays are the preferred method for measuring levels of VEGF, PlGF, or sFlt-1. Particularly preferred, for ease and simplicity of detection, and its quantitative nature, is the sandwich or double antibody assay of which a number of variations
20 exist, all of which are contemplated by the present invention. For example, in a typical sandwich assay, unlabeled antibody that recognizes the antigen (i.e., sFlt-1, PlGF, or VEGF polypeptide) is immobilized on a solid phase, e.g. microtiter plate, and the sample to be tested is added. After a certain period of incubation to allow formation of an antibody-antigen complex, a second antibody, labeled with a reporter
25 molecule capable of inducing a detectable signal, is added and incubation is continued to allow sufficient time for binding with the antigen at a different site, resulting with a formation of a complex of antibody-antigen-labeled antibody. The presence of the antigen is determined by observation of a signal which may be quantitated by comparison with control samples containing known amounts of antigen.

30 Elevated serum levels of sFlt-1 are considered a positive indicator of pre-eclampsia. This value of sFlt-1 may be preferentially 2 ng/ml or more. Additionally, any detectable alteration in levels of sFlt-1, VEGF, or PlGF relative to normal levels is indicative of eclampsia, pre-eclampsia, or the propensity to develop such

conditions. Preferably, sFlt-1 is measured, more preferably measurement of VEGF and PlGF are combined with this measurement, and most preferably all three proteins (or mRNA levels indicative of protein levels) are measured. In additional preferred embodiments, the body mass index (BMI) and gestational age of the fetus is also measured and included the diagnostic metric.

In another embodiment, the PAAI (sFlt-1/ VEGF + PlGF) is used as an anti-angiogenic index that is diagnostic of pre-eclampsia, eclampsia, or the propensity to develop such conditions. If the PAAI is greater than 10, more preferably greater than 20, then the subject is considered to have pre-eclampsia, eclampsia, or to be in imminent risk of developing the same. The PAAI (sFlt-1/ VEGF + PlGF) ratio is merely one example of a useful metric that may be used as a diagnostic indicator. It is not intended to limit the invention. Virtually any metric that detects an alteration in the levels of any of sFlt-1, PlGF, or VEGF in a subject relative to a normal control may be used as a diagnostic indicator.

Expression levels of particular nucleic acids or polypeptides may be correlated with a particular disease state (e.g., pre-eclampsia or eclampsia), and thus are useful in diagnosis. Oligonucleotides or longer fragments derived from a sFlt-1, PlGF, or VEGF nucleic acid sequence may be used as a probe not only to monitor expression, but also to identify subjects having a genetic variation, mutation, or polymorphism in an sFlt-1, PlGF, or VEGF nucleic acid molecule that are indicative of a predisposition to develop the conditions. Such polymorphisms are known to the skilled artisan and are described, for example, by Parry et al. (*Eur. J Immunogenet.* 26:321-3, 1999). A survey of the GenBank database (www.ncbi.nlm.nih.gov) reveals at least 330 known polymorphisms in the gene and the promoter region of Flt-1/sFlt-1. These polymorphisms may affect sFlt-1 nucleic acid or polypeptide expression levels or biological activity. Detection of genetic variation, mutation, or polymorphism relative to a normal, reference sample can be as a diagnostic indicator of pre-eclampsia, eclampsia, or the propensity to develop pre-eclampsia or eclampsia.

Such genetic alterations may be present in the promoter sequence, an open reading frame, intronic sequence, or untranslated 3' region of an sFlt-1 gene. Information related to genetic alterations can be used to diagnose a subject as having pre-eclampsia, eclampsia, or a propensity to develop such conditions. As noted throughout, specific alterations in the levels of biological activity of sFlt-1, VEGF,

and/or PlGF can be correlated with the likelihood of pre-eclampsia or eclampsia, or the predisposition to the same. As a result, one skilled in the art, having detected a given mutation, can then assay one or more metrics of the biological activity of the protein to determine if the mutation causes or increases the likelihood of pre-

5 eclampsia or eclampsia.

In one embodiment, a subject having pre-eclampsia, eclampsia, or a propensity to develop such conditions will show an increase in the expression of a nucleic acid encoding sFlt-1 or an alteration in PlGF or VEGF levels. Methods for detecting such alterations are standard in the art and are described in Ausubel et al.,
10 *supra*. In one example northern blotting or real-time PCR is used to detect sFlt-1, PlGF, or VEGF mRNA levels.

In another embodiment, hybridization with PCR probes that are capable of detecting an sFlt-1 nucleic acid molecule, including genomic sequences, or closely related molecules, may be used to hybridize to a nucleic acid sequence derived from a
15 subject having pre-eclampsia or eclampsia or at risk of developing such conditions. The specificity of the probe, whether it is made from a highly specific region, e.g., the 5' regulatory region, or from a less specific region, e.g., a conserved motif, and the stringency of the hybridization or amplification (maximal, high, intermediate, or low), determine whether the probe hybridizes to a naturally occurring sequence, allelic
20 variants, or other related sequences. Hybridization techniques may be used to identify mutations indicative of a pre-eclampsia or eclampsia in an sFlt-1 nucleic acid molecule, or may be used to monitor expression levels of a gene encoding an sFlt-1 polypeptide (for example, by Northern analysis, Ausubel et al., *supra*).

In yet another embodiment, humans may be diagnosed for a propensity to
25 develop pre-eclampsia or eclampsia by direct analysis of the sequence of an sFlt-1, VEGF, or PlGF nucleic acid molecule.

A subject having pre-eclampsia, eclampsia, or a propensity to develop such conditions will show an increase in the expression of an sFlt-1 polypeptide. The sFlt-1 polypeptide can include full-length sFlt-1, degradation products, alternatively
30 spliced isoforms of sFlt-1, enzymatic cleavage products of sFlt-1, and the like. An antibody that specifically binds an sFlt-1 polypeptide may be used for the diagnosis of pre-eclampsia or eclampsia or to identify a subject at risk of developing such conditions. A variety of protocols for measuring an alteration in the expression of

such polypeptides are known, including immunological methods (such as ELISAs and RIAs), and provide a basis for diagnosing pre-eclampsia or eclampsia or a risk of developing such conditions. Again, an increase in the level of the sFlt-1 polypeptide is diagnostic of a subject having pre-eclampsia, eclampsia, or a propensity to develop such conditions.

In one embodiment, the level of sFlt-1, VEGF, or PlGF polypeptide or nucleic acid, or any combination thereof, is measured at least two different times and an alteration in the levels as compared to normal reference levels over time is used as an indicator of pre-eclampsia, eclampsia, or the propensity to develop such conditions.

In another embodiment, the level of sFlt-1, VEGF, or PlGF polypeptide or nucleic acid, or any combination thereof is compared to the level in a reference sample.

The level of sFlt-1, VEGF, or PlGF polypeptide can also be compared to a standard curve to determine if it falls within "normal ranges" of the level of polypeptide. In this embodiment, a standard curve is established for each of the polypeptides using purified or recombinant forms (e.g., greater than 80%, 90%, 95%, 99% or 100% pure) of the polypeptide for comparison. A standard curve is generated and the concentration of the polypeptide is determined by comparison to a standard curve established for the same polypeptide. For example, a standard curve can be established for sFlt-1 and a subject sample that, when compared to the standard curve, has sFlt-1 concentrations greater than 2 ng/mL is considered indicative of pre-eclampsia, eclampsia, or the propensity to develop such conditions.

The level of sFlt-1, VEGF, or PlGF in the bodily fluids of a subject having pre-eclampsia, eclampsia, or the propensity to develop such conditions may be altered (increased or decreased) by as little as 10%, 20%, 30%, or 40%, or by as much as 50%, 60%, 70%, 80%, or 90% or more relative to the level of sFlt-1, VEGF, or PlGF in a normal control. The level of sFlt-1 present in the bodily fluids of a subject having pre-eclampsia, eclampsia, or the propensity to develop such conditions may be increased by 1.5-fold, 2-fold, 3-fold, 4-fold or even by as much as 10-fold or more relative to levels in a normal control subject.

In one embodiment, a subject sample of a bodily fluid (e.g., urine, plasma, serum, amniotic fluid, or cerebrospinal fluid) is collected early in pregnancy prior to the onset of pre-eclampsia symptoms. In another example, the sample can be a tissue or cell collected early in pregnancy prior to the onset of pre-eclampsia symptoms.

Non-limiting examples include placental tissue, placental cells, endothelial cells, and leukocytes such as monocytes. In humans, for example, maternal blood serum samples are collected from the antecubital vein of pregnant women during the first, second, or third trimesters of the pregnancy. Preferably, the assay is carried out
5 during the first trimester, for example, at 4, 6, 8, 10, or 12 weeks, or during the second trimester, for example at 14, 16, 18, 20, 22, or 24 weeks. Such assays may also be conducted at the end of the second trimester or the third trimester, for example at 26, 28, 30, 32, 34, 36, 37, 38, 39, or 40 weeks. It is preferable that levels of sFlt-1, VEGF, or PlGF be measured twice during this period of time. For the diagnosis of
10 post-partum pre-eclampsia or eclampsia, assays for sFlt-1, VEGF, or PlGF may be carried out postpartum.

In one particular example, serial blood samples can be collected during pregnancy and the levels of soluble sFlt-1 determined by ELISA. In one study using this technique, the alternatively spliced mRNA encoding sFlt-1 is highly expressed by
15 trophoblast cells and the protein was readily detectable in the plasma of pregnant women. It was observed that the levels of sFlt-1 increased approximately 3-fold between 20 and 36 weeks gestation. Levels were observed to be significantly higher in high-risk women who subsequently went on to develop pre-eclampsia (Charnock-Jones *et al.*, *J. Soc. Gynecol. Investig.* 10(2):230, 2003).

In one preferred embodiment, PlGF polypeptide levels are measured in a bodily fluid sample, preferably urine, and used as a diagnostic indicator of pre-eclampsia, eclampsia, or the propensity to develop the same. Measurements of PlGF polypeptide levels in the urine can also be used as an initial assessment of the potential risk for pre-eclampsia or eclampsia and a woman determined to be "at risk"
25 by PlGF measurements can then undergo additional diagnostic assays such as the ones described herein or known in the art. In one example, a woman diagnosed with a risk of developing pre-eclampsia or eclampsia by PlGF polypeptide measurement in a urine sample is further monitored by serum analysis of VEGF, sFlt-1, and/or PlGF levels as described above. In another example, the PAAI is determined using the
30 serum values for each of these polypeptides. A woman identified as having a risk of developing pre-eclampsia or eclampsia by urine analysis for PlGF can be monitored

regularly prior to pregnancy, throughout the pregnancy (e.g., every month, every three weeks, every two weeks, weekly, every third day, every other day, or daily), or after the pregnancy.

The free form of PlGF has an average molecular weight of about 30 kDa and is small enough to be filtered by the kidney and released into the urine. PlGF, when complexed to sFlt-1, has a much greater molecular weight and would therefore not be released into the urine. Although not wishing to be bound by theory, the inventors have discovered that during pre-eclampsia, when the levels of sFlt-1 are increased, sFlt-1 can complex to PlGF, thereby reducing the levels of free PlGF released into the urine. As a result, urine analysis for free PlGF levels can be used to diagnose pre-eclampsia or eclampsia or a patient at risk for having the same. In order to detect free PlGF, it is preferred that an antibody that specifically recognizes free PlGF is used for these assays. Such an antibody can recognize, for example, the sFlt-1 binding domain of PlGF. Examples of such a specific antibody include the capture antibody used in the human PlGF ELISA kit (catalog # DGG00, R &D Systems, Minneapolis, MN), monoclonal anti-placental growth factor (clone 37203.111, Sigma-Aldrich, St. Louis, MO). These antibodies recognize specific sequences in the N-terminal region of human PlGF protein. The sFlt1 binding region to PlGF is between amino acids 39-105 of the PlGF protein, wherein the total length of PlGF varies from 149 to 221 amino acids depending on the isoform of PlGF. Additional preferred antibodies include any antibody that recognizes the N-terminal region (preferably between amino acids 39-105 of PlGF) and that will specifically bind to free PlGF and not PlGF bound to sFlt-1. Antibodies raised to C-terminus will not have this property.

As with any of the diagnostic assays of the invention, PlGF levels in a subject sample can be compared to a reference sample to determine relative levels. A reference sample can be a urine sample from a patient having pre-eclampsia (generally having a level of free PlGF less than 400 pg/ml, preferably less than 200 pg/ml) or from a normal urine sample (having a PlGF concentration ranging from 200 pg/ml to 800 pg/ml) depending on the desired use of the diagnostic assay. The PlGF levels can also be compared to a reference value or standard to determine absolute levels. The reference value or standard can be determined using a standard curve established based on purified or recombinant forms (e.g., greater than 80%, 90%, 95%, 99% or 100% pure) of PlGF for comparison. A value of PlGF less than 400

pg/ml, preferably less than 200 pg/ml, and most preferably less than 100 pg/ml or a PlGF/creatinine value less than 200 pg/mg of creatinine and preferably less than 100 pg/mg of creatinine is considered a diagnostic indicator of pre-eclampsia or eclampsia or a patient at risk for having the same. For standard curves, recombinant PlGF ranging from 10 pg/ml to 1 ng/ml can be used. Other examples of recombinant proteins that can be used to generate the standard curves include specific peptides that encompass the amino terminus of PlGF, preferably amino acids 39-105 of the PlGF protein (the region of PlGF that binds to sFlt-1). Alternatively, a recombinant PlGF/VEGF heterodimer (available commercially as catalog # 297-VP, R & D Systems, MN) can also be used. The latter has the advantage that this protein may also be used to generate the VEGF standard curve in the measurement of free VEGF.

ELISA assays are the preferred method for measuring levels of free PlGF. Particularly preferred, for ease and simplicity of detection, and its quantitative nature, is the sandwich or double antibody ELISA assay of which a number of variations exist, all of which are contemplated by the present invention. For example, in a typical sandwich assay, unlabeled antibody that recognizes the PlGF polypeptide is immobilized on a solid phase, e.g. microtiter plate, and the sample to be tested is added. After a certain period of incubation to allow formation of an antibody-antigen complex, a second antibody, labeled with a reporter molecule capable of inducing a detectable signal, is added and incubation is continued to allow sufficient time for binding with the antigen at a different site, resulting with a formation of a complex of antibody-antigen-labeled antibody. The presence of the antigen is determined by observation of a signal which may be quantitated by comparison with control samples containing known amounts of antigen.

In an example of the quantitative sandwich ELISA, a solid support (e.g., a microtiter plate or a membrane) is pre-coated with an anti-PlGF binding agent (e.g., a primary antibody). Standards or samples are added to the substrate and PlGF, if present, will bind to the antibody. A standardized preparation of enzyme-conjugated antibody that also recognizes PlGF is then added to "sandwich" the PlGF now immobilized on the plate. The substrate is added and the enzyme and substrate are allowed to react over a short incubation period. The enzyme-substrate reaction is terminated and the change is measured by art known methods (e.g., by eye, using a spectrophotometer, or measuring chemiluminescence). Such an assay can be used to

determine the relative level of PlGF (e.g., as compared to the level in a reference sample, standard or level) or to determine the absolute concentration of PlGF. If so desired, the concentration of PlGF can be determined using a set of calibration standards of purified PlGF at varying concentrations. The calibration standards are
5 assayed at the same time as the sample and are used to produce a standard curve measured by, for example, optical density, versus PlGF concentration. The concentration of PlGF in the sample is then determined by comparing, for example, the optical density of the samples to the standard curve. The concentrations of PlGF during normal pregnancy during mid-gestation and late-gestation will range from 200-
10 800 pg/ml depending on the gestational age of the mother. Any value of urinary PlGF less than 400 pg/ml, preferably less than 200 pg/ml or a value of urinary PlGF less than 200 pg/mg of creatinine will be diagnostic of preeclampsia. In general, the standard curves on the ELISA kit will include recombinant or purified PlGF at concentrations ranging from 10 pg/ml – 1ng/ml of PlGF.

15 In another example, an assay for detecting PlGF in a urine sample includes a membrane having an immobilized PlGF binding agent that is detectably labeled in a manner that can distinguish between the PlGF when it is bound to free PlGF and when it is not bound to free PlGF. Preferred labels include fluorescent labels. The membrane is exposed to the sample for a time sufficient to allow binding of the PlGF
20 binding agent to free PlGF present in the sample. The labeled PlGF binding agent bound to the free PlGF is then measured. Such an assay can be used to determine the relative level of PlGF (e.g., as compared to the level from a reference sample or standard or level) or to determine the absolute concentration of PlGF as described above. Preferred assays for the measurement of binding include fluorescence
25 immunoassays.

In another example, an assay for detecting PlGF in a urine sample includes a membrane having a dehydrated labeled (e.g., for colorimetric detection) PlGF binding agent (primary agent) and an immobilized anti-PlGF binding agent (secondary agent). The membrane is exposed to the sample. The sample rehydrates the labeled PlGF
30 binding agent and if PlGF is present in the sample, it will bind to the PlGF binding agent. The PlGF-primary agent complex will move down the membrane by capillary

movement and will interact with the immobilized secondary agent. This interaction will produce a visible line from the colorimetric label at the position at which the secondary agent is immobilized.

In another example, an assay for detecting PlGF in a urine sample includes a
5 membrane having a dehydrated labeled (e.g., for colorimetric detection) PlGF binding agent (primary agent), and an immobilized anti-PlGF binding agent (secondary agent). The membrane also includes purified PlGF at a threshold concentration also immobilized on the membrane. In this example, the membrane is exposed to the urine sample. The sample rehydrates the labeled primary agent and if PlGF is present in the
10 sample at a concentration greater than the threshold concentration, it will bind to the PlGF binding agent. The PlGF-labeled primary agent complex will move down the membrane by capillary movement. As the primary agent is already bound to the PlGF from the sample, it will not bind to the immobilized purified PlGF and no visible line will appear at this "test" position. The PlGF-primary agent complex will continue
15 down the membrane and will interact with the immobilized secondary agent. This interaction will produce a visible line from the colorimetric label at the "control" position at which the anti-PlGF binding agent is immobilized. In this example, only one visible line will appear and will indicate a PlGF concentration above a threshold concentration. If the concentration of PlGF is below the threshold concentration, the
20 labeled primary agent will bind to the immobilized PlGF and a visible line will appear at this "test" location as well as at the "control" location. The test assay can also include multiple test lines aimed at detecting several concentrations of PlGF in the sample. Such a graded assay is described in U.S. Patent No. 6,660,534.

In another example, a similar membrane based assay is used but is based on
25 standard sandwich ELISA methods. In this example, the membrane includes a reaction zone having an immobilized primary PlGF binding agent conjugated to an enzyme; a test zone having another immobilized PlGF binding agent that binds to a region of PlGF not bound by the first PlGF binding agent, and a control zone having an immobilized substance that recognizes the primary PlGF binding agent. In both
30 the test zone and the control zone a detectable substrate for the enzyme conjugated to the first immobilized PlGF binding agent is included. The membrane is exposed to the sample and the sample moves to the reaction zone by capillary action. If PlGF is present in the sample, it binds to the first immobilized PlGF binding agent conjugated

to an enzyme and forms a complex which is then carried along by capillary flow to the test zone. The PlGF-immobilized PlGF binding agent conjugated to an enzyme complex then binds to the second PlGF binding agent and forms a visible line at the location of the immobilized second PlGF binding agent (the "test" zone). The
5 remaining first PlGF binding agent is carried along by capillary flow and will bind to the immobilized substance that recognizes or binds to the first binding agent and produce a visible line at this location (the "control" zone). If PlGF is not present in the sample, only the second line will appear at the control zone. In preferred
10 embodiments, the first and second PlGF binding agents are antibodies and the agent that recognizes or binds to the first binding agent is a secondary anti-immunoglobulin antibody that specifically recognizes the immunoglobulin of the first antibody. The intensity of the line in the test zone can be compared to assays using a standard amount of purified PlGF protein to determine if the sample contains PlGF above or below a threshold concentration.

15 In any of the assays described herein, normal pregnant serum can be used as an additional control and the activity of PlGF can be measured and quantified as a percentage of PlGF activity measured from normal pregnant serum.

For any of the assays described herein, the sample can be any bodily fluid. A urine sample is preferred for the PlGF-based diagnostic assays. The membrane can be
20 in a standard dipstick type format or lateral flow format. The dipstick type of assay is known in the art for such assays as pregnancy detection (measuring hormone levels in that case) or urinalysis detection of creatinine or albumin in the diagnosis of kidney disease. Examples of various formats of dipstick type assays are described in U.S. Patent No. 6,660,534, incorporated herein by reference.

25 Any of the above PlGF detection assays can be used alone or in combination with additional diagnostic assays described herein or in the art. In a preferred embodiment, the PlGF diagnostic assay is used as an initial screen followed by assays for the measurement of serum sFlt-1, PlGF and/or VEGF levels as described herein. In this way "at risk" patients can be identified and carefully monitored or screened
30 further for even greater diagnostic accuracy.

In preferred embodiments of any of the above-described PlGF-based diagnostic assays, the PlGF binding agent is preferably a primary antibody that recognizes PlGF or a protein or peptide that interacts with PlGF. The secondary anti-

PlGF binding agent is preferably a secondary antibody that recognizes the primary antibody or a protein that binds to the primary antibody (e.g., Protein A or Protein G), or an antibody that specifically binds the peptide that interacts with PlGF. In embodiments where the PlGF binding agent is labeled with an enzyme, the enzyme
5 used preferably catalyzes a colorimetric reaction that can be detected by eye and/or measured by spectrophotometry. Non-limiting examples of preferred enzyme/substrate combinations are horseradish peroxidase/TMB, β -galactosidase/XGAL, and alkaline/phosphatase/1,2 dioxetane. For embodiments that include a labeled PlGF binding agent, preferred labels include colorimetric (e.g.,
10 colloidal gold), chemiluminescent, or fluorescent labels.

In veterinary practice, assays may be carried out at any time during the pregnancy, but are, preferably, carried out early in pregnancy, prior to the onset of pre-eclampsia symptoms. Given that the term of pregnancies varies widely between species, the timing of the assay will be determined by a veterinarian, but will
15 generally correspond to the timing of assays during a human pregnancy.

The diagnostic methods described herein can be used individually or in combination with any other diagnostic method described herein for a more accurate diagnosis of the presence of, severity of, or estimated time of onset of pre-eclampsia or eclampsia. In addition, the diagnostic methods described herein can be used in
20 combination with any other diagnostic methods determined to be useful for the accurate diagnosis of the presence of, severity of, or estimated time of onset of pre-eclampsia or eclampsia.

The diagnostic methods described herein can also be used to monitor and manage pre-eclampsia or eclampsia in a subject. In one example, if a subject is
25 determined to have a serum sFlt-1 protein level of 10 ng/mL and a serum level of free PlGF of 100 pg/mL, then VEGF can be administered until the serum PlGF level rises to approximately 400 pg/mL. In this embodiment, the levels of sFlt-1, PlGF, and VEGF, or any and all of these, are measured repeatedly as a method of not only diagnosing disease but monitoring the treatment and management of the pre-
30 eclampsia and eclampsia. As described above, in normal pregnancies, urinary levels of PlGF range from 200-800 pg/ml or 200-800 pg/mg of creatinine after 20 weeks of

gestation. A value of PlGF less than 400 pg/ml, preferably less than 200 pg/ml or 200 pg/mg of creatinine in a urine sample is considered diagnostic of preeclampsia or a propensity to develop pre-eclampsia.

The invention also features diagnostic assays for the detection of a cardiovascular condition or a propensity to develop a cardiovascular condition. In a preferred embodiment, sFlt-1 levels are measured in women with a history of pre-eclampsia or eclampsia and compared to sFlt-1 levels from a reference sample. Reference samples preferably include samples taken from women with previous pregnancies and no history of pre-eclampsia or eclampsia. Alterations in the levels of sFlt-1 polypeptide or nucleic acid as compared to the reference sample can be used to diagnose a cardiovascular condition or to predict a propensity to develop a cardiovascular condition. Alterations in the nucleic acid sequence of sFlt-1, PlGF, or VEGF as compared to a reference sequence can also be used to diagnose a cardiovascular condition or to predict a propensity to develop a cardiovascular condition. Any of the diagnostic methods and metrics described above can be used to monitor women with a history of pre-eclampsia or eclampsia post-partum or to diagnose a cardiovascular condition or to predict a propensity to develop a cardiovascular condition. Post-partum monitoring can be performed on a regular basis (e.g., once a month, once every six months, yearly, every other year, or less frequently) to assist in the diagnosis, prediction, or prevention of future cardiovascular events or conditions.

Diagnostic Kits

The invention also provides for a diagnostic test kit that includes the components required to carry out any of the diagnostic assays described above and instructions for the use of the components to diagnose pre-eclampsia or eclampsia or the propensity to develop pre-eclampsia or eclampsia. For example, a diagnostic test kit can include antibodies to sFlt-1, VEGF, or PlGF, and components useful for detecting, and more preferably evaluating, binding between the antibodies and the sFlt-1, VEGF, or PlGF polypeptide. For detection, either the antibody or the sFlt-1, VEGF, or PlGF polypeptide is labeled, and either the antibody or the sFlt-1, VEGF, or PlGF polypeptide is substrate-bound, such that the sFlt-1, VEGF, or PlGF polypeptide-antibody interaction can be established by determining the amount of

label attached to the substrate following binding between the antibody and the sFlt-1, VEGF, or PlGF polypeptide. In one example, the kit includes a PlGF binding agent and components for detecting the presence of PlGF. A conventional ELISA or a sandwich ELSIA is a common, art-known method for detecting antibody-substrate interaction and can be provided with the kit of the invention. sFlt-1, VEGF, or PlGF polypeptides can be detected in virtually any bodily fluid including, but not limited to urine, serum, plasma, saliva, amniotic fluid, or cerebrospinal fluid. A kit that determines an alteration in the level of sFlt-1, VEGF, or PlGF polypeptide relative to a reference, such as the level present in a normal control, is useful as a diagnostic kit in the methods of the invention. The kit can also include purified proteins to be used as standards in the assay used to detect the level of sFlt-1, VEGF, or PlGF. Desirably, the kit will contain instructions for the use of the kit. In one example, the kit contains instructions for the use of the kit for the diagnosis of pre-eclampsia, eclampsia, or the propensity to develop pre-eclampsia or eclampsia. In another example, the kit contains instructions for the diagnosis of cardiovascular conditions or the propensity to develop cardiovascular conditions. In yet another example, the kit contains instructions for the use of the kit to monitor therapeutic treatment or dosage regimens.

In one embodiment of the invention, such a kit includes a solid support (e.g., a membrane or a microtiter plate) coated with a primary agent (e.g., an antibody or protein that recognizes the antigen), standard solutions of purified protein for preparation of a standard curve, a body fluid (e.g. serum or urine) control for quality testing of the analytical run, a secondary agent (e.g., a second antibody reactive with a second epitope in the antigen to be detected or an antibody or protein that recognizes the primary antibody) conjugated to a label or an enzyme such as horse radish peroxidase or otherwise labelled, a substrate solution, a stopping solution, a washing buffer and an instruction manual.

Screening Assays

As discussed above, the expression of an sFlt-1 nucleic acid or polypeptide is increased in a subject having pre-eclampsia, eclampsia, or a propensity to develop such conditions. Based on these discoveries, compositions of the invention are useful for the high-throughput low-cost screening of candidate compounds to identify those

that modulate the expression of a sFlt-1, VEGF, or PlGF polypeptide or nucleic acid molecule whose expression is altered in a subject having a pre-eclampsia or eclampsia.

Any number of methods are available for carrying out screening assays to
5 identify new candidate compounds that alter the expression of a sFlt-1, VEGF, or PlGF nucleic acid molecule. In one working example, candidate compounds are added at varying concentrations to the culture medium of cultured cells expressing a sFlt-1, VEGF, or PlGF nucleic acid sequence. Gene expression is then measured, for example, by microarray analysis, Northern blot analysis (Ausubel et al., *supra*), or
10 RT-PCR, using any appropriate fragment prepared from the nucleic acid molecule as a hybridization probe. The level of gene expression in the presence of the candidate compound is compared to the level measured in a control culture medium lacking the candidate compound. A compound that promotes an alteration such as an increase in the expression of a VEGF or PlGF gene, nucleic acid molecule, or polypeptide, or a
15 decrease in the expression of an sFlt-1 gene, nucleic acid molecule, or polypeptide, or a functional equivalent thereof, is considered useful in the invention; such a molecule may be used, for example, as a therapeutic to treat pre-eclampsia or eclampsia in a subject.

In another working example, the effect of candidate compounds may be
20 measured at the level of polypeptide production using the same general approach and standard immunological techniques, such as Western blotting or immunoprecipitation with an antibody specific for a sFlt-1, VEGF, or PlGF polypeptide. For example, immunoassays may be used to detect or monitor the expression of at least one of the polypeptides of the invention in an organism. Polyclonal or monoclonal antibodies
25 (produced as described above) that are capable of binding to such a polypeptide may be used in any standard immunoassay format (e.g., ELISA, western blot, or RIA assay) to measure the level of the polypeptide. In some embodiments, a compound that promotes an alteration such as an increase in the expression or biological activity of a VEGF or PlGF polypeptide or a decrease in the expression or biological activity
30 of an sFlt-1 polypeptide is considered particularly useful. Again, such a molecule may be used, for example, as a therapeutic to delay, ameliorate, or treat a pre-eclampsia or eclampsia, or the symptoms of a pre-eclampsia or eclampsia, in a subject.

In yet another working example, candidate compounds may be screened for those that specifically bind to an sFlt-1, VEGF, or PlGF polypeptide. The efficacy of such a candidate compound is dependent upon its ability to interact with such a polypeptide or a functional equivalent thereof. Such an interaction can be readily
5 assayed using any number of standard binding techniques and functional assays (e.g., those described in Ausubel et al., *supra*). In one embodiment, a candidate compound may be tested *in vitro* for its ability to specifically bind a polypeptide of the invention. In another embodiment, a candidate compound is tested for its ability to decrease the biological activity of an sFlt-1 polypeptide by decreasing binding of an sFlt-1
10 polypeptide and a growth factor, such as VEGF or PlGF.

In another working example, an sFlt-1, VEGF, or PlGF nucleic acid is expressed as a transcriptional or translational fusion with a detectable reporter, and expressed in an isolated cell (e.g., mammalian or insect cell) under the control of a heterologous promoter, such as an inducible promoter. The cell expressing the fusion
15 protein is then contacted with a candidate compound, and the expression of the detectable reporter in that cell is compared to the expression of the detectable reporter in an untreated control cell. A candidate compound that decreases the expression of an sFlt-1 detectable reporter, or that increases the expression of a VEGF or PlGF detectable reporter is a compound that is useful for the treatment of pre-eclampsia or
20 eclampsia. In preferred embodiments, the candidate compound alters the expression of a reporter gene fused to a nucleic acid or nucleic acid.

In one particular working example, a candidate compound that binds to an sFlt-1 polypeptide may be identified using a chromatography-based technique. For example, a recombinant polypeptide of the invention may be purified by standard
25 techniques from cells engineered to express the polypeptide (e.g., those described above) and may be immobilized on a column. A solution of candidate compounds is then passed through the column, and a compound specific for the sFlt-1 polypeptide is identified on the basis of its ability to bind to the polypeptide and be immobilized on the column. To isolate the compound, the column is washed to remove non-
30 specifically bound molecules, and the compound of interest is then released from the column and collected. Similar methods may be used to isolate a compound bound to a polypeptide microarray. Compounds isolated by this method (or any other appropriate method) may, if desired, be further purified (e.g., by high performance

liquid chromatography). In addition, these candidate compounds may be tested for their ability to decrease the activity of an sFlt-1 polypeptide or to increase the activity of a VEGF signaling pathway (e.g., as described herein). Compounds isolated by this approach may also be used, for example, as therapeutics to treat pre-eclampsia or eclampsia in a human subject. Compounds that are identified as binding to a polypeptide of the invention with an affinity constant less than or equal to 10 mM are considered particularly useful in the invention. Alternatively, any *in vivo* protein interaction detection system, for example, any two-hybrid assay may be utilized to identify compounds or proteins that bind to a polypeptide of the invention.

10 Potential antagonists include organic molecules, peptides, peptide mimetics, polypeptides, nucleic acids, and antibodies that bind to an sFlt-1 nucleic acid sequence or sFlt-1 polypeptide.

sFlt-1 DNA sequences may also be used in the discovery and development of a therapeutic compound for the treatment of pre-eclampsia or eclampsia. The encoded protein, upon expression, can be used as a target for the screening of drugs. Additionally, the DNA sequences encoding the amino terminal regions of the encoded protein or Shine-Delgarno or other translation facilitating sequences of the respective mRNA can be used to construct sequences that decrease the expression of an sFlt-1 coding sequence. Such sequences may be isolated by standard techniques (Ausubel et al., *supra*).

20 Optionally, compounds identified in any of the above-described assays may be confirmed as useful in an assay for compounds that decrease the biological activity of sFlt-1 or that increase the activity of a VEGF signaling pathway.

Small molecules of the invention preferably have a molecular weight below 2,000 daltons, more preferably between 300 and 1,000 daltons, and most preferably between 400 and 700 daltons. It is preferred that these small molecules are organic molecules.

Therapeutics targeting the VEGF signaling pathway

30 VEGF is a potent endothelial cell-specific mitogen that stimulates angiogenesis, vascular hyperpermeability, and vasodilation. Three tyrosine-kinase signaling receptors for VEGF have been identified. VEGF-receptor binding triggers a signaling cascade that results in tyrosine phosphorylation of phospholipase C γ 1,

leading to increases in intracellular levels of inositol 1,4,5-triphosphate and increases in intracellular calcium that activates nitric oxide synthase to produce nitric oxide (NO). NO formation activates guanylate cyclase within vascular smooth muscle cells and endothelial cells, causing cGMP production. This NO/cGMP cascade is thought to mediate the vasoactive effects of VEGF. Another pathway that appears to be involved in mediating the vasoactive effects of VEGF is the prostacyclin release pathway. VEGF induces PGI₂ production via activation of phospholipase A₂ as a consequence of initiation of the MAPK cascade.

Increased VEGF levels are useful for the treatment of pre-eclampsia and eclampsia. Therapeutic compounds that target VEGF signaling pathways, or components of a VEGF signaling pathway, and enhance the activity of a VEGF signaling pathway are also useful for the treatment of pre-eclampsia and eclampsia. Such compounds include sildenafil, prostacyclin analogs, such as Flolan, Remodulin, and Tracleer.

Test compounds and extracts

In general, compounds capable of decreasing the activity of a sFlt-1 polypeptide or increasing the activity of VEGF or PlGF are identified from large libraries of both natural product or synthetic (or semi-synthetic) extracts or chemical libraries or from polypeptide or nucleic acid libraries, according to methods known in the art. Those skilled in the field of drug discovery and development will understand that the precise source of test extracts or compounds is not critical to the screening procedure(s) of the invention. Compounds used in screens may include known compounds (for example, known therapeutics used for other diseases or disorders). Alternatively, virtually any number of unknown chemical extracts or compounds can be screened using the methods described herein. Examples of such extracts or compounds include, but are not limited to, plant-, fungal-, prokaryotic- or animal-based extracts, fermentation broths, and synthetic compounds, as well as modification of existing compounds. Numerous methods are also available for generating random or directed synthesis (e.g., semi-synthesis or total synthesis) of any number of chemical compounds, including, but not limited to, saccharide-, lipid-, peptide-, and nucleic acid-based compounds. Synthetic compound libraries are commercially available from Brandon Associates (Merrimack, NH) and Aldrich Chemical

(Milwaukee, WI). Alternatively, libraries of natural compounds in the form of bacterial, fungal, plant, and animal extracts are commercially available from a number of sources, including Biotics (Sussex, UK), Xenova (Slough, UK), Harbor Branch Oceanographics Institute (Ft. Pierce, FL), and PharmaMar, U.S.A. (Cambridge, MA).

- 5 In addition, natural and synthetically produced libraries are produced, if desired, according to methods known in the art, e.g., by standard extraction and fractionation methods. Furthermore, if desired, any library or compound is readily modified using standard chemical, physical, or biochemical methods.

- 10 In addition, those skilled in the art of drug discovery and development readily understand that methods for dereplication (e.g., taxonomic dereplication, biological dereplication, and chemical dereplication, or any combination thereof) or the elimination of replicates or repeats of materials already known for their mol-
- disrupting activity should be employed whenever possible.

- When a crude extract is found to decrease the activity of an sFlt-1 polypeptide, or to bind to sFlt-1 polypeptide, further fractionation of the positive lead extract is necessary to isolate chemical constituents responsible for the observed effect. Thus, the goal of the extraction, fractionation, and purification process is the careful characterization and identification of a chemical entity within the crude extract that decreases the activity of an sFlt-1 polypeptide. Methods of fractionation and
- 15 purification of such heterogeneous extracts are known in the art. If desired, compounds shown to be useful as therapeutics for the treatment of a human pre-eclampsia or eclampsia are chemically modified according to methods known in the art.

25 **Therapeutics**

- The present invention features methods for treating or preventing pre-eclampsia or eclampsia in a subject. Preferably, the therapeutic is administered during pregnancy for the treatment or prevention of pre-eclampsia or eclampsia or after pregnancy to treat post-partum pre-eclampsia or eclampsia. Techniques and
- 30 dosages for administration vary depending on the type of compound (e.g., chemical compound, antibody, antisense, or nucleic acid vector) and are well known to those skilled in the art or are readily determined.

Therapeutic compounds of the present invention may be administered with a pharmaceutically acceptable diluent, carrier, or excipient, in unit dosage form.

Administration may be parenteral, intravenous, subcutaneous, oral or local by direct injection into the amniotic fluid. Intravenous delivery by continuous infusion is the preferred method for administering the therapeutic compounds of the present invention.

The composition can be in the form of a pill, tablet, capsule, liquid, or sustained release tablet for oral administration; or a liquid for intravenous, subcutaneous or parenteral administration; or a polymer or other sustained release vehicle for local administration.

Methods well known in the art for making formulations are found, for example, in "Remington: The Science and Practice of Pharmacy" (20th ed., ed. A.R. Gennaro AR., 2000, Lippincott Williams & Wilkins, Philadelphia, PA). Formulations for parenteral administration may, for example, contain excipients, sterile water, saline, polyalkylene glycols such as polyethylene glycol, oils of vegetable origin, or hydrogenated naphthalenes. Biocompatible, biodegradable lactide polymer, lactide/glycolide copolymer, or polyoxyethylene-polyoxypropylene copolymers may be used to control the release of the compounds. Nanoparticulate formulations (e.g., biodegradable nanoparticles, solid lipid nanoparticles, liposomes) may be used to control the biodistribution of the compounds. Other potentially useful parenteral delivery systems include ethylene-vinyl acetate copolymer particles, osmotic pumps, implantable infusion systems, and liposomes. The concentration of the compound in the formulation varies depending upon a number of factors, including the dosage of the drug to be administered, and the route of administration.

The compound may be optionally administered as a pharmaceutically acceptable salts, such as non-toxic acid addition salts or metal complexes that are commonly used in the pharmaceutical industry. Examples of acid addition salts include organic acids such as acetic, lactic, pamoic, maleic, citric, malic, ascorbic, succinic, benzoic, palmitic, suberic, salicylic, tartaric, methanesulfonic, toluenesulfonic, or trifluoroacetic acids or the like; polymeric acids such as tannic acid, carboxymethyl cellulose, or the like; and inorganic acid such as hydrochloric acid, hydrobromic acid, sulfuric acid phosphoric acid, or the like. Metal complexes include zinc, iron, and the like.

Formulations for oral use include tablets containing the active ingredient(s) in a mixture with non-toxic pharmaceutically acceptable excipients. These excipients may be, for example, inert diluents or fillers (e.g., sucrose and sorbitol), lubricating agents, glidants, and anti-adhesives (e.g., magnesium stearate, zinc stearate, stearic acid, silicas, hydrogenated vegetable oils, or talc).

Formulations for oral use may also be provided as chewable tablets, or as hard gelatin capsules wherein the active ingredient is mixed with an inert solid diluent, or as soft gelatin capsules wherein the active ingredient is mixed with water or an oil medium.

The dosage and the timing of administering the compound depends on various clinical factors including the overall health of the subject and the severity of the symptoms of pre-eclampsia. In general, once pre-eclampsia or a propensity to develop pre-eclampsia is detected, continuous infusion of the purified protein is used to treat or prevent further progression of the condition. Treatment can be continued for a period of time ranging from 1 to 100 days, more preferably 1 to 60 days, and most preferably 1 to 20 days, or until the completion of pregnancy. Dosages vary depending on each compound and the severity of the condition and are titrated to achieve a steady-state blood serum concentration ranging from 1 to 500 ng/mL VEGF or PlGF, or both, preferably 1 to 100 ng/mL, more preferably 5 to 50 ng/mL and most preferably 5 to 10 ng/mL VEGF or PlGF, or both.

The diagnostic methods described herein can also be used to monitor the pre-eclampsia or eclampsia during therapy or to determine the dosages of therapeutic compounds. In one example, a therapeutic compound is administered and the PAAI is determined during the course of therapy. If the PAAI is less than 10, preferably less than 20, then the therapeutic dosage is considered to be an effective dosage.

Methods to increase VEGF or PlGF protein expression

The present invention features methods for increasing the levels of VEGF and PlGF in a subject diagnosed with pre-eclampsia or eclampsia. The increased levels of VEGF or PlGF can be achieved using several different methodologies that are described below, among others.

Purified proteins

In a preferred embodiment of the present invention, purified forms of VEGF or PlGF or both are administered to the subject in order to treat or prevent pre-eclampsia or eclampsia.

- 5 Purified VEGF or VEGF-like proteins include any protein with an amino acid sequence that is homologous, more desirably, substantially identical to the amino acid sequence of VEGF, or any VEGF family member, that can induce angiogenesis or that is capable of promoting selective growth of vascular endothelial cells or umbilical vein endothelial cells. One example of a purified VEGF compound is human
10 recombinant VEGF-165 from Genentech, Inc. (San Francisco, CA). Another example is human recombinant VEGF-121 from Scios, Inc (Fremont, CA).

- Purified PlGF or PlGF-like proteins include any protein with an amino acid sequence that is homologous, more desirably, substantially identical to the amino acid sequence of PlGF, or any PlGF family member, that can induce angiogenesis or that is
15 capable of promoting selective growth of vascular endothelial cells or umbilical vein endothelial cells. An example of commercially available purified PlGF is human recombinant PlGF from R&D Systems (catalog # 264-PG, R&D Systems, Minneapolis, MN). ThromboGenics Ltd is also developing a purified form of PlGF for the treatment of ischemic stroke; presumably this form of PlGF would be effective
20 for the applications described in the present invention.

Therapeutic compounds that increase VEGF or PlGF activity

- The present invention provides for the use of any compound known to stimulate or increase blood serum levels of VEGF or PlGF, or the biological activity
25 of these polypeptides, for the treatment or prevention of pre-eclampsia in a subject. These compounds can be used alone or in combination with the purified proteins described above or any of the other methods used to increase VEGF or PlGF protein levels described herein.

- One example of a compound shown to stimulate VEGF production is nicotine.
30 Although smoking poses many risks for the overall health of a pregnant woman and her developing fetus, nicotine by itself is believed to be safer than cigarettes and can be used for short-term therapy on high-risk subjects. Examples include Nicorette (nicotine polacrilex), which is an over-the-counter nicotine gum product made by

SmithKline Beecham and NicoDerm CQ, which is an over-the counter nicotine patch made by Hoechst Marion Roussel Inc. (formerly Marion Merrell Dow). Nicotine delivered via tobacco is specifically excluded from the methods of the invention where the patient has not also been diagnosed using the methods of the invention.

5 Nicotine is administered after the diagnosis of pre-eclampsia or eclampsia using either the patch or gum. Dosages vary depending on the severity of the condition and the overall health of the subject. In general, the manufacturer's instructions are followed to achieve a serum level of nicotine ranging from 5 to 500 ng/mL, more preferably 5 to 100 ng/mL, and most preferably 50 to 100 ng/mL.

10 Theophylline is another example of an additional compound that can be used to treat or prevent pre-eclampsia or eclampsia. Theophylline is a bronchodilator which is often used for the treatment of asthma and is available under many brand names (e.g., Aerolate Sr, Asmalix, Elxophyllin, etc.) as well as the generic. Methods of administration and dosages vary with each manufacturer and are chosen based on
15 the overall health of the subject and the severity of the condition. In general, daily dosages range from 1 to 500 mg, more preferably 100 to 400 mg, and most preferably 250 to 350 mg given twice a day to achieve a serum level of theophylline of 5 to 50 µg/mL.

 Adenosine is another example of an additional compound that can be used to
20 treat or prevent pre-eclampsia or eclampsia. Adenosine (Fujisawa Pharmaceutical Co.) is commonly used as an anti-hypertensive drug. Methods of administration and dosages vary with each manufacturer and are chosen based on the overall health of the subject and the severity of the condition. In general, a daily dosage of 50 mg/kg given twice a day is typical for adenosine.

25 Nifedipine is another example of an additional compound that can be used to treat or prevent pre-eclampsia or eclampsia. Nifedipine (Bayer Pharmaceuticals) is commonly used as an anti-hypertensive drug. Methods of administration and dosages vary with each manufacturer and are chosen based on the overall health of the subject and the severity of the condition. In general, a daily dosage of 1-2 mg/kg given twice
30 a day orally or subcutaneously is typical for nifedipine.

 Minoxidil is another example of an additional compound that can be used to treat or prevent pre-eclampsia or eclampsia. Minoxidil is commonly used as an anti-hypertensive drug. Methods of administration and dosages vary with each

manufacturer and are chosen based on the overall health of the subject and the severity of the condition. In general, a daily dosage of 0.25 to 1.0 mg/kg given twice a day orally or subcutaneously is typical for minoxidil.

5 Magnesium sulfate is another example of an additional compound that can be used to treat or prevent pre-eclampsia or eclampsia. Magnesium sulfate is a generic drug which is typically used as an anti-hypertensive drug. Methods of administration and dosages vary with each manufacturer and are chosen based on the overall health of the subject and the severity of the condition. In general, a daily dosage of 1-2 gm given intravenously ever four hours is a typical dosage for magnesium sulfate.

10 In addition to the use of compounds that can increase serum levels of VEGF or PlGF, the invention provides for the use of any chronic hypertension medications used in combination with any of the VEGF or PlGF directed compounds. Medications used for the treatment of hypertension during pregnancy include methyldopa, hydralazine hydrochloride, or labetalol. For each of these medications,
15 modes of administration and dosages are determined by the physician and by the manufacturer's instructions.

Therapeutic nucleic acids

 Recent work has shown that the delivery of nucleic acid (DNA or RNA)
20 capable of expressing an endothelial cell mitogen such as VEGF to the site of a blood vessel injury will induce proliferation and reendothelialization of the injured vessel. While the present invention does not relate to blood vessel injury, the techniques for the delivery of nucleic acid encoding endothelial cell mitogens such as VEGF and PlGF used in these studies can also be employed in the present invention. These
25 techniques are described in U.S. Patent Nos. 5,830,879 and 6,258,787 and are incorporated herein by reference.

 In the present invention the nucleic acid may be any nucleic acid (DNA or RNA) including genomic DNA, cDNA, and mRNA, encoding VEGF or PlGF or any VEGF or PlGF family members. The nucleic acid may also include any nucleic acid
30 which encodes a protein shown to bind to the sFlt-1 receptor. The nucleic acids encoding the desired protein may be obtained using routine procedures in the art, e.g. recombinant DNA, PCR amplification.

Therapeutic nucleic acids that inhibit sFlt-1 expression

The present invention also features the use of antisense nucleobase oligomers to downregulate expression of sFlt-1 mRNA directly. By binding to the complementary nucleic acid sequence (the sense or coding strand), antisense nucleobase oligomers are able to inhibit protein expression presumably through the enzymatic cleavage of the RNA strand by RNAse H. Preferably the antisense nucleobase oligomer is capable of reducing sFlt-1 protein expression in a cell that expresses excess levels of sFlt-1. Preferably the decrease in sFlt-1 protein expression is at least 10% relative to cells treated with a control oligonucleotide, more preferably 25%, and most preferably 50% or greater. Methods for selecting and preparing antisense nucleobase oligomers are well known in the art. For an example of the use of antisense nucleobase oligomers to downregulate VEGF expression see U.S. Patent No. 6,410,322, incorporated herein by reference. Methods for assaying levels of protein expression are also well known in the art and include western blotting, immunoprecipitation, and ELISA.

The present invention also features the use of RNA interference (RNAi) to inhibit expression of sFlt-1. RNA interference (RNAi) is a recently discovered mechanism of post-transcriptional gene silencing (PTGS) in which double-stranded RNA (dsRNA) corresponding to a gene or mRNA of interest is introduced into an organism resulting in the degradation of the corresponding mRNA. In the RNAi reaction, both the sense and anti-sense strands of a dsRNA molecule are processed into small RNA fragments or segments ranging in length from 21 to 23 nucleotides (nt) and having 2-nucleotide 3' tails. Alternatively, synthetic dsRNAs, which are 21 to 23 nt in length and have 2-nucleotide 3' tails, can be synthesized, purified and used in the reaction. These 21 to 23 nt dsRNAs are known as "guide RNAs" or "short interfering RNAs" (siRNAs).

The siRNA duplexes then bind to a nuclease complex composed of proteins that target and destroy endogenous mRNAs having homology to the siRNA within the complex. Although the identity of the proteins within the complex remains unclear, the function of the complex is to target the homologous mRNA molecule through base pairing interactions between one of the siRNA strands and the endogenous

mRNA. The mRNA is then cleaved approximately 12 nt from the 3' terminus of the siRNA and degraded. In this manner, specific genes can be targeted and degraded, thereby resulting in a loss of protein expression from the targeted gene.

The specific requirements and modifications of dsRNA are described in PCT Publication No. WO01/75164 (incorporated herein by reference). While dsRNA molecules can vary in length, it is most preferable to use siRNA molecules which are 21- to 23- nucleotide dsRNAs with characteristic 2- to 3- nucleotide 3' overhanging ends typically either (2'-deoxy)thymidine or uracil. The siRNAs typically comprise a 3' hydroxyl group. Single stranded siRNA as well as blunt ended forms of dsRNA can also be used. In order to further enhance the stability of the RNA, the 3' overhangs can be stabilized against degradation. In one such embodiment, the RNA is stabilized by including purine nucleotides, such as adenosine or guanosine. Alternatively, substitution of pyrimidine nucleotides by modified analogs, e.g., substitution of uridine 2-nucleotide overhangs by (2'-deoxy)thymide is tolerated and does not affect the efficiency of RNAi. The absence of a 2' hydroxyl group significantly enhances the nuclease resistance of the overhang in tissue culture medium.

Alternatively siRNA can be prepared using any of the methods set forth in PCT Publication No. WO01/75164 (incorporated herein by reference) or using standard procedures for *in vitro* transcription of RNA and dsRNA annealing procedures as described in Elbashir et al. (*Genes & Dev.*, 15:188-200, 2001). siRNAs are also obtained as described in Elbashir et al. by incubation of dsRNA that corresponds to a sequence of the target gene in a cell-free *Drosophila* lysate from syncytial blastoderm *Drosophila* embryos under conditions in which the dsRNA is processed to generate siRNAs of about 21 to about 23 nucleotides, which are then isolated using techniques known to those of skill in the art. For example, gel electrophoresis can be used to separate the 21-23 nt RNAs and the RNAs can then be eluted from the gel slices. In addition, chromatography (e.g., size exclusion chromatography), glycerol gradient centrifugation, and affinity purification with antibody can be used to isolate the 21 to 23 nt RNAs.

In the present invention, the dsRNA, or siRNA, is complementary to the mRNA sequence of an sFlt-1 mRNA and can reduce or inhibit expression of sFlt-1. Preferably, the decrease in sFlt-1 protein expression is at least 10% relative to cells

treated with a control dsRNA or siRNA, more preferably 25%, and most preferably at least 50%. Methods for assaying levels of protein expression are also well known in the art and include western blotting, immunoprecipitation, and ELISA.

5 In the present invention, the nucleic acids used include any modification that enhances the stability or function of the nucleic acid in any way. Examples include modifications to the phosphate backbone, the internucleotide linkage, or to the sugar moiety.

To simplify the manipulation and handling of the nucleic acid encoding the sFlt-1 binding protein, the nucleic acid is preferably inserted into a cassette where it is
10 operably linked to a promoter. The promoter must be capable of driving expression of the sFlt-1 binding protein in the desired target host cell. The selection of appropriate promoters can readily be accomplished. Preferably, one would use a high expression promoter. An example of a suitable promoter is the 763-base-pair cytomegalovirus (CMV) promoter. The Rous sarcoma virus (RSV) (Davis, et al.,
15 *Hum. Gene Ther.* 4:151-159, 1993) and mouse mammary tumor virus (MMTV) promoters may also be used. Certain proteins can be expressed using their native promoter. Other elements that can enhance expression can also be included (e.g., enhancers or a system that results in high levels of expression such as a tat gene and tar element). The recombinant vector can be a plasmid vector such as pUC118,
20 pBR322, or other known plasmid vectors, that includes, for example, an *E. coli* origin of replication (see, Sambrook, et al., *Molecular Cloning: A Laboratory Manual*, Cold Spring Harbor Laboratory press, 1989). The plasmid vector may also include a selectable marker such as the β lactamase gene for ampicillin resistance, provided that the marker polypeptide does not adversely affect the metabolism of the organism
25 being treated. The cassette can also be bound to a nucleic acid binding moiety in a synthetic delivery system, such as the system disclosed in PCT Publication No. WO95/22618.

The nucleic acid can be introduced into the cells by any means appropriate for the vector employed. Many such methods are well known in the art (Sambrook et al.,
30 *supra*, and Watson et al., "Recombinant DNA", Chapter 12, 2d edition, Scientific American Books, 1992). Recombinant vectors can be transferred by methods such as calcium phosphate precipitation, electroporation, liposome-mediated transfection, gene gun, microinjection, viral capsid-mediated transfer, polybrene-mediated transfer,

or protoplast fusion. For a review of the procedures for liposome preparation, targeting and delivery of contents, see Mannino and Gould-Fogerite, (*Bio Techniques*, 6:682-690, 1988), Felgner and Holm, (*Bethesda Res. Lab. Focus*, 11:21, 1989) and Maurer (*Bethesda Res. Lab. Focus*, 11:25, 1989).

5 Transfer of the recombinant vector (either plasmid vector or viral vectors) can be accomplished through direct injection into the amniotic fluid or intravenous delivery.

 Gene delivery using adenoviral vectors or adeno-associated vectors (AAV) can also be used. Adenoviruses are present in a large number of animal species, are
10 not very pathogenic, and can replicate equally well in dividing and quiescent cells. As a general rule, adenoviruses used for gene delivery are lacking one or more genes required for viral replication. Replication-defective recombinant adenoviral vectors used for the delivery of VEGF, PlGF or any sFlt-1 binding protein, can be produced in accordance with art-known techniques (see Quantin et al., *Proc. Natl. Acad. Sci.*
15 *USA*, 89:2581-2584, 1992; Stratford-Perricadet et al., *J. Clin. Invest.*, 90:626-630, 1992; and Rosenfeld et al., *Cell*, 68:143-155, 1992). For an example of the use of gene therapy *in utero* see U.S. Patent No. 6,399,585.

 A variety of methods are available for transfection, or introduction, of dsRNA or oligonucleotides into mammalian cells. For example, there are several
20 commercially available transfection reagents including but not limited to: TransIT-TKO™ (Mirus, Cat. # MIR 2150), Transmessenger™ (Qiagen, Cat. # 301525), and Oligofectamine™ (Invitrogen, Cat. # MIR 12252-011). Protocols for each transfection reagent are available from the manufacturer.

 Once transferred, the nucleic acid is expressed by the cells at the site of injury
25 for a period of time sufficient to increase blood serum levels of VEGF, PlGF, or any other sFlt-1 binding protein. Because the vectors containing the nucleic acid are not normally incorporated into the genome of the cells, expression of the protein of interest takes place for only a limited time. Typically, the protein is expressed at therapeutic levels for about two days to several weeks, preferably for about one to two
30 weeks. Re-application of the DNA can be utilized to provide additional periods of expression of the therapeutic protein. Recent examples of gene therapy using VEGF for the treatment of vascular disease in mammals can be found in Deodato et al. (*Gene*

Ther., 9:777-785, 2002); Isner et al. (*Human Gene Ther.*, 12:1593-1594, 2001); Lai et al. (*Gene Ther.*, 9:804-813, 2002); and reviewed in Freedman and Isner (*Ann. Intern. Med.*, 136:54-71, 2002) and Isner JM (*Nature*, 415:234-239, 2002).

5 Assays for gene and protein expression

The following methods can be used to evaluate protein or gene expression and determine efficacy for any of the above-mentioned methods for increasing VEGF, PlGF or any other sFlt-1 binding protein levels, or for decreasing sFlt-1 protein levels.

Blood serum from the subject is measured for levels of VEGF, PlGF, or any protein ligand known to bind to sFlt-1. Methods used to measure serum levels of proteins include ELISA, western blotting, or immunoassays using specific antibodies. In addition, biological activity can be determined using an *in vitro* angiogenesis assay to determine if the subject's blood has converted from an anti-angiogenic state to a pro-angiogenic state. Such assays are described above in Example 2.

Blood serum samples from the subject can also be measured for levels of VEGF, PlGF or sFlt-1 nucleic acid levels. There are several art-known methods to assay for gene expression. Some examples include the preparation of RNA from the blood samples of the subject and the use of the RNA for northern blotting, PCR based amplification, or RNase protection assays.

20

Use of antibodies for therapeutic treatment

The elevated levels of sFlt-1 found in the serum samples taken from pregnant women suffering from pre-eclampsia suggests that sFlt-1 is acting as a "physiologic sink" to bind to and deplete the trophoblast cells and maternal endothelial cells of functional VEGF and PlGF. The use of compounds, such as antibodies, to bind to sFlt-1 and block VEGF or PlGF binding, may help prevent or treat pre-eclampsia or eclampsia, by producing an increase in free VEGF or PlGF. Such an increase would allow for an increase in trophoblast proliferation, migration and angiogenesis required for placental development and fetal nourishment, and for systemic maternal endothelial cell health.

30

The present invention provides antibodies that bind specifically to the ligand-binding domain of sFlt-1. The antibodies are used to inhibit sFlt-1 and the most effective mechanism is believed to be through direct blocking of the binding sites for

VEGF or PlGF, however, other mechanisms cannot be ruled out. Methods for the preparation and use of antibodies for therapeutic purposes are described in several patents including U.S. Patent Numbers 6,054,297; 5,821,337; 6,365,157; and 6,165,464 and are incorporated herein by reference. Antibodies can be polyclonal or monoclonal; monoclonal antibodies are preferred.

Monoclonal antibodies, particularly those derived from rodents including mice, have been used for the treatment of various diseases; however, there are limitations to their use including the induction of a human anti-mouse immunoglobulin response that causes rapid clearance and a reduction in the efficacy of the treatment. For example, a major limitation in the clinical use of rodent monoclonal antibodies is an anti-globulin response during therapy (Miller et al., *Blood*, 62:988-995 1983; Schroff et al., *Cancer Res.*, 45:879-885, 1985).

The art has attempted to overcome this problem by constructing "chimeric" antibodies in which an animal antigen-binding variable domain is coupled to a human constant domain (U.S. Pat. No. 4,816,567; Morrison et al., *Proc. Natl. Acad. Sci. USA*, 81:6851-6855, 1984; Boulianne et al., *Nature*, 312:643-646, 1984; Neuberger et al., *Nature*, 314:268-270, 1985). The production and use of such chimeric antibodies are described below.

Competitive inhibition of ligand binding to sFlt-1 is useful for the prevention or treatment of pre-eclampsia or eclampsia. Antibodies directed to sFlt-1 can block binding of VEGF or PlGF to sFlt-1 resulting in increased levels of VEGF or PlGF. Such an increase can result in a rescue of endothelial dysfunction and a shift in the balance of pro-angiogenic /anti-angiogenic factors towards angiogenesis.

A cocktail of the monoclonal antibodies of the present invention can be used as an effective treatment for pre-eclampsia or eclampsia. The cocktail may include as few as two, three, or four different antibodies or as many as six, eight, or ten different antibodies. In addition, the antibodies of the present invention can be combined with an anti-hypertensive drug (e.g., methyldopa, hydralazine hydrochloride, or labetalol) or any other medication used to treat pre-eclampsia, eclampsia, or the symptoms associated with pre-eclampsia or eclampsia.

Preparation of Antibodies

Monoclonal antibodies that specifically bind to the sFlt-1 receptor may be produced by methods known in the art. These methods include the immunological method described by Kohler and Milstein (*Nature*, 256: 495-497, 1975) and Campbell
5 ("Monoclonal Antibody Technology, The Production and Characterization of Rodent and Human Hybridomas" in Burdon et al., Eds., Laboratory Techniques in Biochemistry and Molecular Biology, Volume 13, Elsevier Science Publishers, Amsterdam, 1985), as well as by the recombinant DNA method described by Huse et al. (*Science*, 246, 1275-1281, 1989).

10 Monoclonal antibodies may be prepared from supernatants of cultured hybridoma cells or from ascites induced by intra-peritoneal inoculation of hybridoma cells into mice. The hybridoma technique described originally by Kohler and Milstein (*Eur. J. Immunol*, 6, 511-519, 1976) has been widely applied to produce hybrid cell lines that secrete high levels of monoclonal antibodies against many
15 specific antigens.

The route and schedule of immunization of the host animal or cultured antibody-producing cells therefrom are generally in keeping with established and conventional techniques for antibody stimulation and production. Typically, mice are used as the test model, however, any mammalian subject including human subjects or
20 antibody producing cells therefrom can be manipulated according to the processes of this invention to serve as the basis for production of mammalian, including human, hybrid cell lines.

After immunization, immune lymphoid cells are fused with myeloma cells to generate a hybrid cell line that can be cultivated and subcultivated indefinitely, to
25 produce large quantities of monoclonal antibodies. For purposes of this invention, the immune lymphoid cells selected for fusion are lymphocytes and their normal differentiated progeny, taken either from lymph node tissue or spleen tissue from immunized animals. The use of spleen cells is preferred, since they offer a more concentrated and convenient source of antibody producing cells with respect to the
30 mouse system. The myeloma cells provide the basis for continuous propagation of the fused hybrid. Myeloma cells are tumor cells derived from plasma cells. Murine myeloma cell lines can be obtained, for example, from the American Type Culture Collection (ATCC; Manassas, VA). Human myeloma and mouse-human

heteromyeloma cell lines have also been described (Kozbor et al., *J. Immunol.*, 133:3001-3005, 1984; Brodeur et al., *Monoclonal Antibody Production Techniques and Applications*, Marcel Dekker, Inc., New York, pp. 51-63, 1987).

The hybrid cell lines can be maintained *in vitro* in cell culture media. Once
5 the hybridoma cell line is established, it can be maintained on a variety of
nutritionally adequate media such as hypoxanthine-aminopterin-thymidine (HAT)
medium. Moreover, the hybrid cell lines can be stored and preserved in any number
of conventional ways, including freezing and storage under liquid nitrogen. Frozen
cell lines can be revived and cultured indefinitely with resumed synthesis and
10 secretion of monoclonal antibody. The secreted antibody is recovered from tissue
culture supernatant by conventional methods such as precipitation, ion exchange
chromatography, affinity chromatography, or the like.

The antibody may be prepared in any mammal, including mice, rats, rabbits,
goats, and humans. The antibody may be a member of one of the following
15 immunoglobulin classes: IgG, IgM, IgA, IgD, or IgE, and the subclasses thereof, and
preferably is an IgG antibody.

While the preferred animal for producing monoclonal antibodies is mouse, the
invention is not so limited; in fact, human antibodies may be used and may prove to
be preferable. Such antibodies can be obtained by using human hybridomas (Cole et
20 al., "Monoclonal Antibodies and Cancer Therapy", Alan R. Liss Inc., p. 77-96, 1985).
In the present invention, techniques developed for the production of chimeric
antibodies by splicing the genes from a mouse antibody molecule of appropriate
antigen specificity together with genes from a human antibody molecule can be used
(Morrison et al., *Proc. Natl. Acad. Sci.* 81, 6851-6855, 1984; Neuberger et al., *Nature*
25 312, 604-608, 1984; Takeda et al., *Nature* 314, 452-454, 1985); such antibodies are
within the scope of this invention and are described below.

As another alternative to the cell fusion technique, Epstein-Barr virus (EBV)
immortalized B cells are used to produce the monoclonal antibodies of the present
invention (Crawford D. et al., *J. of Gen. Virol.*, 64:697-700, 1983; Kozbor and Roder,
30 *J. Immunol.*, 4:1275-1280, 1981; Kozbor et al., *Methods in Enzymology*, 121:120-140,
1986). In general, the procedure consists of isolating Epstein-Barr virus from a
suitable source, generally an infected cell line, and exposing the target antibody
secreting cells to supernatants containing the virus. The cells are washed, and

cultured in an appropriate cell culture medium. Subsequently, virally transformed cells present in the cell culture can be identified by the presence of the Epstein-Barr viral nuclear antigen, and transformed antibody secreting cells can be identified using standard methods known in the art. Other methods for producing monoclonal
5 antibodies, such as recombinant DNA, are also included within the scope of the invention.

Preparation of sFlt-1 Immunogens

sFlt-1 may be used by itself as an immunogen, or may be attached to a carrier
10 protein or to other objects, such as sepharose beads. sFlt-1 may be purified from cells known to express the endogenous protein such as human umbilical vein endothelial cells (HUVEC; Kendall et al., *Biochem. Biophys. Res. Comm.*, 226:324-328, 1996). Additionally, nucleic acid molecules that encode sFlt-1, or portions thereof, can be inserted into known vectors for expression in host cells using standard recombinant
15 DNA techniques. Suitable host cells for sFlt-1 expression include baculovirus cells (e.g., Sf9 cells), bacterial cells (e.g., *E. coli*), and mammalian cells (e.g., NIH3T3 cells).

In addition, peptides can be synthesized and used as immunogens. The methods for making antibody to peptides are well known in the art and generally
20 require coupling the peptide to a suitable carrier molecule, such as serum albumin. Peptides include any amino acid sequence that is substantially identical to any part of the sFlt-1 amino acid sequence corresponding to GenBank accession number U01134. Peptides can be any length, preferably 10 amino acids or greater, more preferably 25 amino acids or greater, and most preferably 40, 50, 60, 70, 80, or 100 amino acids or
25 greater. Preferably, the amino acid sequences are at least 60%, more preferably 85%, and, most preferably 95% identical to the sequence of U01134. The peptides can be commercially obtained or made using techniques well known in the art, such as, for example, the Merrifield solid-phase method (*Science*, 232:341-347, 1985). The procedure may use commercially available synthesizers such as a Biosearch 9500
30 automated peptide machine, with cleavage of the blocked amino acids being achieved with hydrogen fluoride, and the peptides purified by preparative HPLC using a Waters Delta Prep 3000 instrument, on a 15-20 μ m Vydac C4 PrepPAK column.

Functional equivalents of antibodies

The invention also includes functional equivalents of the antibodies described in this specification. Functional equivalents include polypeptides with amino acid sequences substantially identical to the amino acid sequence of the variable or
5 hypervariable regions of the antibodies of the invention. Functional equivalents have binding characteristics comparable to those of the antibodies, and include, for example, chimerized, humanized and single chain antibodies as well as fragments thereof. Methods of producing such functional equivalents are disclosed, for example, in PCT Publication No. WO93/21319; European Patent Application No.
10 239,400; PCT Publication No. WO89/09622; European Patent Application No. 338,745; European Patent Application No. 332424; and U.S. Patent No. 4,816,567; each of which is herein incorporated by reference.

Chimerized antibodies preferably have constant regions derived substantially or exclusively from human antibody constant regions and variable regions derived
15 substantially or exclusively from the sequence of the variable region from a mammal other than a human. Such humanized antibodies are chimeric immunoglobulins, immunoglobulin chains or fragments thereof (such as Fv, Fab, Fab', F(ab')₂ or other antigen-binding subsequences of antibodies) which contain minimal sequence derived from non-human immunoglobulin. Methods for humanizing non-human antibodies
20 are well known in the art (for reviews see Vaswani and Hamilton, *Ann Allergy Asthma Immunol.*, 81:105-119, 1998 and Carter, *Nature Reviews Cancer*, 1:118-129, 2001). Generally, a humanized antibody has one or more amino acid residues introduced into it from a source that is non-human. These non-human amino acid residues are often referred to as import residues, which are typically taken from an
25 import variable domain. Humanization can be essentially performed following the methods known in the art (Jones et al., *Nature*, 321:522-525, 1986; Riechmann et al., *Nature*, 332:323-329, 1988; and Verhoeyen et al., *Science*, 239:1534-1536 1988), by substituting rodent CDRs or other CDR sequences for the corresponding sequences of a human antibody. Accordingly, such humanized antibodies are chimeric antibodies
30 wherein substantially less than an intact human variable domain has been substituted by the corresponding sequence from a non-human species (see for example, U.S. Patent No. 4,816,567). In practice, humanized antibodies are typically human

antibodies in which some CDR residues and possibly some FR residues are substituted by residues from analogous sites in rodent antibodies (Presta, *Curr. Op. Struct. Biol.*, 2:593-596, 1992).

Additional methods for the preparation of humanized antibodies can be found in U.S. Patent Nos. 5,821,337, and 6,054,297, and Carter, (*supra*) which are all
5 incorporated herein by reference. The humanized antibody is selected from any class of immunoglobulins, including IgM, IgG, IgD, IgA and IgE, and any isotype, including IgG₁, IgG₂, IgG₃, and IgG₄. Where cytotoxic activity is not needed, such as in the present invention, the constant domain is preferably of the IgG₂ class. The
10 humanized antibody may comprise sequences from more than one class or isotype, and selecting particular constant domains to optimize desired effector functions is within the ordinary skill in the art.

Human antibodies can also be produced using various techniques known in the art, including phage display libraries (Marks et al., *J. Mol. Biol.*, 222:581-597, 1991
15 and Winter et al. *Annu. Rev. Immunol.*, 12:433-455, 1994). The techniques of Cole et al. and Boerner et al. are also useful for the preparation of human monoclonal antibodies (Cole et al., *supra*; Boerner et al., *J. Immunol.*, 147: 86-95, 1991).

Suitable mammals other than a human include any mammal from which monoclonal antibodies may be made. Examples of mammals other than a human
20 include, for example a rabbit, rat, mouse, horse, goat, or primate; a mouse is preferred.

Functional equivalents of antibodies also include single-chain antibody fragments, also known as single-chain antibodies (scFvs). Single-chain antibody fragments are recombinant polypeptides which typically bind antigens or receptors;
25 these fragments contain at least one fragment of an antibody variable heavy-chain amino acid sequence (V_H) tethered to at least one fragment of an antibody variable light-chain sequence (V_L) with or without one or more interconnecting linkers. Such a linker may be a short, flexible peptide selected to assure that the proper three-dimensional folding of the V_L and V_H domains occurs once they are linked so as to
30 maintain the target molecule binding-specificity of the whole antibody from which the single-chain antibody fragment is derived. Generally, the carboxyl terminus of the V_L or V_H sequence is covalently linked by such a peptide linker to the amino acid terminus of a complementary V_L and V_H sequence. Single-chain antibody fragments

can be generated by molecular cloning, antibody phage display library or similar techniques. These proteins can be produced either in eukaryotic cells or prokaryotic cells, including bacteria.

Single-chain antibody fragments contain amino acid sequences having at least one of the variable regions or CDRs of the whole antibodies described in this specification, but are lacking some or all of the constant domains of those antibodies. These constant domains are not necessary for antigen binding, but constitute a major portion of the structure of whole antibodies. Single-chain antibody fragments may therefore overcome some of the problems associated with the use of antibodies containing part or all of a constant domain. For example, single-chain antibody fragments tend to be free of undesired interactions between biological molecules and the heavy-chain constant region, or other unwanted biological activity. Additionally, single-chain antibody fragments are considerably smaller than whole antibodies and may therefore have greater capillary permeability than whole antibodies, allowing single-chain antibody fragments to localize and bind to target antigen-binding sites more efficiently. Also, antibody fragments can be produced on a relatively large scale in prokaryotic cells, thus facilitating their production. Furthermore, the relatively small size of single-chain antibody fragments makes them less likely than whole antibodies to provoke an immune response in a recipient.

Functional equivalents further include fragments of antibodies that have the same or comparable binding characteristics to those of the whole antibody. Such fragments may contain one or both Fab fragments or the $F(ab')_2$ fragment. Preferably the antibody fragments contain all six CDRs of the whole antibody, although fragments containing fewer than all of such regions, such as three, four or five CDRs, are also functional.

Further, the functional equivalents may be or may combine members of any one of the following immunoglobulin classes: IgG, IgM, IgA, IgD, or IgE, and the subclasses thereof.

30

Preparation of Functional Equivalents of Antibodies

Equivalents of antibodies are prepared by methods known in the art. For example, fragments of antibodies may be prepared enzymatically from whole antibodies. Preferably, equivalents of antibodies are prepared from DNA encoding
5 such equivalents. DNA encoding fragments of antibodies may be prepared by deleting all but the desired portion of the DNA that encodes the full-length antibody.

DNA encoding chimerized antibodies may be prepared by recombining DNA substantially or exclusively encoding human constant regions and DNA encoding variable regions derived substantially or exclusively from the sequence of the variable
10 region of a mammal other than a human. DNA encoding humanized antibodies may be prepared by recombining DNA encoding constant regions and variable regions other than the CDRs derived substantially or exclusively from the corresponding human antibody regions and DNA encoding CDRs derived substantially or exclusively from a mammal other than a human.

15 Suitable sources of DNA molecules that encode fragments of antibodies include cells, such as hybridomas, that express the full-length antibody. The fragments may be used by themselves as antibody equivalents, or may be recombined into equivalents, as described above.

The DNA deletions and recombinations described in this section may be
20 carried out by known methods, such as those described in the published patent applications listed above.

Antibody Screening and Selection

Monoclonal antibodies are isolated and purified using standard art-known
25 methods. For example, antibodies can be screened using standard art-known methods such as ELISA against the sFlt-1 peptide antigen or western blot analysis. Non-limiting examples of such techniques are described in Examples II and III of U.S. Patent No. 6,365,157, herein incorporated by reference.

Therapeutic Uses of Antibodies

30 When used *in vivo* for the treatment or prevention of pre-eclampsia or eclampsia, the antibodies of the subject invention are administered to the subject in therapeutically effective amounts. Preferably, the antibodies are administered

parenterally or intravenously by continuous infusion. The dose and dosage regimen depends upon the severity of the disease, and the overall health of the subject. The amount of antibody administered is typically in the range of about 0.001 to about 10 mg/kg of subject weight, preferably 0.01 to about 5 mg/kg of subject weight.

5 For parenteral administration, the antibodies are formulated in a unit dosage injectable form (solution, suspension, emulsion) in association with a pharmaceutically acceptable parenteral vehicle. Such vehicles are inherently nontoxic, and non-therapeutic. Examples of such vehicles are water, saline, Ringer's solution, dextrose solution, and 5% human serum albumin. Nonaqueous vehicles
10 such as fixed oils and ethyl oleate may also be used. Liposomes may be used as carriers. The vehicle may contain minor amounts of additives such as substances that enhance isotonicity and chemical stability, e.g., buffers and preservatives. The antibodies typically are formulated in such vehicles at concentrations of about 1 mg/ml to 10 mg/ml.

15

Therapeutic compounds that inhibit sFlt-1

Given that levels of sFlt-1 are increased in subjects having pre-eclampsia, eclampsia, or having a propensity to develop such conditions, any agent that decreases the expression of an sFlt-1 polypeptide or nucleic acid molecule is useful in the
20 methods of the invention. Such agents include small molecules that can disrupt sFlt-1 binding to VEGF or PlGF, antisense nucleobase oligomers, and dsRNAs used to mediate RNA interference.

Combination therapies

25 Optionally, a pre-eclampsia or eclampsia therapeutic may be administered in combination with any other standard pre-eclampsia or eclampsia therapy; such methods are known to the skilled artisan and described herein. A pre-eclampsia or eclampsia therapeutic of the invention may be administered in combination with any compound that increases the activity of a VEGF pathway. Non-limiting examples of
30 agents which also induce endogenous VEGF production include nicotine, minoxidil, nifedipine, adenosine, magnesium sulfate, and theophylline. In one embodiment, PlGF protein can be used in combination with any of the agents which induce endogenous VEGF production listed above.

Subject monitoring

The disease state or treatment of a subject having pre-eclampsia, eclampsia, or a propensity to develop such a condition can be monitored using the methods and compositions of the invention. In one embodiment, the expression of an sFlt-1, VEGF, or PlGF polypeptide present in a bodily fluid, such as urine, plasma, amniotic fluid, or CSF, is monitored. Such monitoring may be useful, for example, in assessing the efficacy of a particular drug in a subject or in assessing disease progression. Therapeutics that decrease the expression of an sFlt-1 nucleic acid molecule or polypeptide or that increase the expression of a VEGF or PlGF nucleic acid molecule or polypeptide are taken as particularly useful in the invention.

Other Embodiments

From the foregoing description, it is apparent that variations and modifications may be made to the invention described herein to adopt it to various usages and conditions. Such embodiments are also within the scope of the following claims.

All publications mentioned in this specification are herein incorporated by reference to the same extent as if each independent publication or patent application was specifically and individually indicated to be incorporated by reference. In addition, U.S. application publication number 2004-0126828 and PCT publication number WO2004/008946A2 are hereby incorporated by reference in their entirety.

What is claimed is:

Claims

1. A method of monitoring the treatment of pre-eclampsia or eclampsia in subject, comprising measuring the level of sFlt-1, VEGF, or PlGF polypeptide in a sample from said subject.
2. The method of claim 1, wherein said measuring of levels is done on two or more occasions and a change in said levels between said measurements is indicative of pre-eclampsia or eclampsia.
3. The method of claim 1, further comprising comparing said level to pre-eclamptic reference, wherein a decrease in the level of sFlt-1 relative to said pre-eclamptic reference indicates an improvement in said pre-eclampsia or eclampsia in said subject.
4. The method of claim 1, further comprising comparing said level to pre-eclamptic reference, wherein an increase in the level of VEGF or PlGF relative to said pre-eclamptic reference indicates an improvement in said pre-eclampsia or eclampsia in said subject.
5. The method of claim 1, wherein said monitoring is used to determine the therapeutic dosage of a compound.
6. The method of claim 5, wherein said compound is administered in a dosage such that the level of sFlt-1 in said subject is less than 2 ng/ml.
7. The method of claim 1, wherein said measuring is done using an immunological assay.
8. The method of claim 1, wherein the level of sFlt-1 is the level of free, bound, or total sFlt-1.

9. The method of claim 1, wherein the level of sFlt-1 is the level of a polypeptide by-product of an sFlt-1 polypeptide which has been degraded or enzymatically cleaved.
10. A method of monitoring the treatment of pre-eclampsia or eclampsia in subject, comprising measuring the levels of at least two of sFlt-1, VEGF, and PlGF polypeptides in a sample from said subject and calculating the relationship between said levels using a metric.
11. The method of claim 10, wherein said metric is a pre-eclampsia anti-angiogenic index (PAAI): $[sFlt-1/VEGF + PlGF]$.
12. The method of claim 11, wherein a PAAI value less than 20 indicates an improvement in said pre-eclampsia or eclampsia.
13. The method of claim 12, wherein a PAAI value less than 10 indicates an improvement in said pre-eclampsia or eclampsia.
14. The method of claim 11, wherein said PAAI is used to determine the dosage of the therapeutic compound.
15. The method of claim 14, wherein the therapeutic compound is administered in a dose such that the PAAI is less than 20 after said therapeutic compound is administered.
16. The method of claim 15, wherein the therapeutic compound is administered in a dose such that the PAAI is less than 10 after said therapeutic compound is administered.
17. The method of claim 10, wherein said measuring is done using an immunological assay.

18. The method of claim 10, wherein said level of sFlt-1 is the level of free, bound, or total sFlt-1.

19. The method of claim 10, wherein said level of sFlt-1 is the level of a polypeptide by-product of an sFlt-1 polypeptide which has been degraded or enzymatically cleaved.

20. The method of claim 10, wherein said level of VEGF or PlGF is the level of free VEGF or PlGF.

21. The method of claim 10, wherein a decrease in the level of sFlt-1 polypeptide relative to a pre-eclamptic reference indicates an improvement in said pre-eclampsia or eclampsia.

22. The method of claim 10, wherein an increase in the level of free VEGF polypeptide relative to a pre-eclamptic reference indicates an improvement in said pre-eclampsia or eclampsia.

23. The method of claim 10, wherein an increase in the level of free PlGF polypeptide relative to a pre-eclamptic reference indicates an improvement in said pre-eclampsia or eclampsia.

24. The method of claim 10, wherein said measuring of levels is done on two or more occasions and a change in said levels between measurements is a diagnostic indicator of pre-eclampsia or eclampsia.

25. A method of monitoring the treatment of pre-eclampsia or eclampsia in subject, comprising measuring the level of sFlt-1, VEGF, or PlGF nucleic acid molecule in a sample from said subject and comparing said level to a reference, wherein an alteration in said level relative to said reference sample diagnoses pre-eclampsia or eclampsia in said subject.

26. The method of claim 25, wherein when the level of VEGF is measured then the level of either sFlt-1 or PlGF is also measured.

27. The method of claim 25, wherein a decrease in the level of sFlt-1 nucleic acid relative to a pre-eclamptic reference indicates an improvement in said pre-eclampsia or eclampsia.

28. The method of claim 25, wherein an increase in the level of VEGF nucleic acid relative to a pre-eclamptic reference indicates an improvement in said pre-eclampsia or eclampsia.

29. The method of claim 25, wherein an increase in the level of PlGF nucleic acid relative to a pre-eclamptic reference indicates an improvement in said pre-eclampsia or eclampsia.

30. The method of claim 25, wherein said measuring of levels is done on two or more occasions and a change in said levels between measurements is a diagnostic indicator of pre-eclampsia or eclampsia.

31. A method of diagnosing a subject as having, or having a propensity to develop, pre-eclampsia or eclampsia, said method comprising measuring the level of free PlGF in a urine sample from said subject.

32. The method of claim 31, wherein a level of free PlGF in said urine sample less than 400 pg/ml measured during mid-gestation or late gestation is a diagnostic indicator of pre-eclampsia or eclampsia or a propensity to develop pre-eclampsia or eclampsia.

33. The method of claim 31, wherein a level of free PlGF in said urine sample less than 200 pg/mg of creatinine in said sample measured during mid-gestation or late gestation is a diagnostic indicator of pre-eclampsia or eclampsia or a propensity to develop pre-eclampsia or eclampsia.

34. The method of claim 31, further comprising comparing said level of free PlGF from said subject to the level of PlGF from a reference sample.

35. The method of claim 34, wherein said reference sample is a prior sample taken from said subject.

36. The method of claim 34, wherein said reference sample is a sample taken from a subject that is pregnant but does not have pre-eclampsia or eclampsia, or a propensity to develop pre-eclampsia or eclampsia.

37. The method of claim 34, wherein a decrease in said free PlGF from said subject compared to said reference sample is a diagnostic indicator of pre-eclampsia or eclampsia or a propensity to develop pre-eclampsia or eclampsia.

38. The method of claim 37, wherein said decrease is a decrease of at least 10% in said level of PlGF from said subject sample as compared to said reference sample.

39. The method of claim 31, further comprising:

(a) measuring the level of at least one of sFlt-1, PlGF, and VEGF polypeptide in a sample from said subject, wherein said sample is a bodily fluid selected from the group consisting of urine, blood, amniotic fluid, serum, plasma, or cerebrospinal fluid; and

(b) comparing said level of sFlt-1, PlGF, or VEGF from said subject to the level of sFlt-1, PlGF, or VEGF polypeptide in a reference sample, wherein an increase in said level of sFlt-1 or a decrease in said level of VEGF or PlGF polypeptide from said subject sample compared to said reference sample is a diagnostic indicator of pre-eclampsia or eclampsia, or a propensity to develop pre-eclampsia or eclampsia.

40. The method of claim 39, wherein the level of sFlt-1 from a sample of serum from said subject is measured.

41. The method of claim 39, wherein the level of sFlt-1 and PlGF from a sample of serum from said subject is measured.

42. The method of claim 39, further comprising calculating the relationship between said levels of at least one of sFlt-1, VEGF, and PlGF from step (a) using a metric, wherein an alteration in the relationship between said levels in the subject sample relative to a reference sample, diagnoses pre-eclampsia or eclampsia or a propensity to develop pre-eclampsia or eclampsia in said subject.

43. The method of claim 42, wherein said metric is a pre-eclampsia anti-angiogenic index (PAAI): $[sFlt-1/VEGF + PlGF]$.

44. The method of claim 43, wherein a PAAI value greater than 20 is a diagnostic indicator of pre-eclampsia or eclampsia.

45. The method of claim 31, wherein said measuring is done using an immunological assay.

46. The method of claim 45, wherein said immunological assay is an ELISA.

47. A method of diagnosing a subject as having or having a propensity to develop pre-eclampsia or eclampsia, said method comprising

(a) obtaining a sample of urine from said subject;

(b) contacting said sample with a solid support, wherein said solid support comprises an immobilized first PlGF binding agent, for a time sufficient to allow binding of said first PlGF binding agent with free PlGF present in said sample;

(c) contacting said solid support after step (b) with a preparation of a second labeled PlGF binding agent, for a time sufficient to allow binding of said second labeled PlGF binding agent to said free PlGF bound to said first immobilized PlGF binding agent;

(d) observing the binding of said second labeled PlGF binding agent to the immobilized PlGF binding agent bound to free PlGF at the position where the PlGF binding agent is immobilized; and

(e) comparing the binding observed in step (d) with the binding observed using a reference sample.

48. The method of claim 47, wherein said reference sample is recombinant PlGF at a concentration of 400 to 800 pg/ml and a decrease in the binding observed in step (d) compared to the binding observed using a reference sample in step (e) is a diagnostic indicator of pre-eclampsia or eclampsia or a propensity to develop pre-eclampsia or eclampsia.

49. The method of claim 47, wherein the label is a colorimetric label.

50. The method of claim 47, wherein said agent that binds PlGF is an antibody, or purified fragment thereof, or a peptide.

51. The method of claim 50, wherein said antibody or fragment thereof specifically binds free PlGF.

52. The method of claim 47, wherein said agent that binds a PlGF binding agent is selected from the group consisting of: an anti-immunoglobulin antibody, protein A, and protein G.

53. A method of diagnosing a subject as having or having a propensity to develop pre-eclampsia or eclampsia, said method comprising:

(a) obtaining a sample of urine from said subject;

(b) contacting said sample with a solid support, wherein said solid support comprises an immobilized PlGF binding agent that is detectably labeled, wherein said contacting is for a time sufficient to allow binding of said first PlGF binding agent to free PlGF present in said sample; and

(c) measuring said labeled PlGF binding agent bound to said free PlGF, wherein said measuring is capable of distinguishing between said bound and unbound PlGF binding agent.

54. The method of claim 53, wherein said label is a fluorescent label.

55. The method of claim 47 or 53, wherein said solid support is a membrane.

56. The method of claim 47 or 53, wherein said subject is a non-pregnant human and said method diagnoses a propensity to develop pre-eclampsia or eclampsia.

57. The method of claim 47 or 53, wherein said subject is a pregnant human.

58. The method of claim 47 or 53, further comprising measuring the level of sFlt-1, PlGF, or VEGF nucleic acid or polypeptide in a sample of bodily fluid from said subject.

59. The method of claim 58, wherein said level of sFlt-1 polypeptide is measured in a sample of serum from said subject.

60. The method of claim 47 or 53, wherein said measuring of levels is done on two or more occasions and a change in said levels between measurements is a diagnostic indicator of pre-eclampsia or eclampsia.

61. A kit for the diagnosis of pre-eclampsia or eclampsia in a subject comprising a PlGF binding agent for detecting free PlGF polypeptide and instructions for its use for the diagnosis of pre-eclampsia or eclampsia or the propensity to develop pre-eclampsia or eclampsia in a subject.

62. The kit of claim 61, further comprising a component for an immunological assay, an enzymatic assay, a fluorescence polarization assay, or a colorimetric assay.

63. The kit of claim 61, wherein said PlGF binding agent is immobilized on a membrane.

64. The kit of claim 63, wherein said membrane is supported on a dipstick structure and the sample is deposited on the membrane by placing the dipstick structure into the sample.

65. The kit of claim 63, wherein said membrane is supported in a lateral flow cassette, and the sample is deposited on the membrane through an opening in the cassette.

66. The kit of claim 61, wherein said kit is used to monitor said subject during therapy.
