EP 1 608 665 B1

Description**Field of the Invention**

[0001] The present invention is directed to novel bisboronic acid-based saccharide sensors. The sensors are of the fluorescent photoinduced electron transfer (PET) type. The sensors can be immobilized on polymer substrates, and fabricated into saccharide sensors in medical devices used for monitoring saccharide levels in patients.

Background of the Invention

[0002] Saccharides are nature's conveyors of energy, and are essential for cell survival. James, T.D. et al., J.Am. Chem. Soc., 117, 8982-8987 (1995) (citing Robertson, R.N., The Lively Membranes, Cambridge University Press, New York, 1983). Defects in glucose transport are associated with various disease states, and fluctuations in glucose levels can be symptomatic or predictive of acute, as well as chronic conditions. *Id.* Thus, the ability to detect and monitor glucose levels in animals, particularly humans, is extremely important.

[0003] Molecular recognition of saccharides or sugars, such as glucose, has proven to be a reliable detection mechanism. Perhaps the most reliable and efficient systems for such detection are those exploiting the phenomena of intramolecular electron transfer, also called photoinduced electron transfer (PET).

[0004] Systems capable of effecting such molecular recognition exhibit both structural and fluorescence changes upon saccharide binding. The change in fluorescence is proportional to the concentration of saccharide in the sample, and so these sensors or dyes can be used for quantitative measurement.

[0005] Among the more popular of these sensors are boronic acid based saccharide sensors. Boronic acid sensors effect reversible formation of strong covalent bonds with the diol functionalities of carbohydrates in the form of cyclic esters. These sensors are superior to other sensor systems involving weaker noncovalent or hydrogen bonded interactions.

[0006] Boronic acid sensors are not without their own shortcomings. The design of a fluorescent sensor based on the boronic acid-saccharide interaction proved difficult due to the lack of sufficient electronic changes found in either the boronic acid moiety or the saccharide moiety. J.Am. Chem. Soc., 117, at 8983. Shinkai's group showed that those disadvantages could be overcome by modifying the boronic acid binding site to create an electron rich center around the boronic acid moiety by, e.g., adding a tertiary amine, which formed an intramolecular five membered ring with the boronic acid moiety. *Id.* They then showed that the 9,10-bis-(aminomethyl)-anthracene skeleton provided a glucose selective sensor by producing a perfect glucose-selective cleft within the molecule. *Id.* These efforts resulted in the so called "Shinkai dyes" (Fig. 1A).

[0007] Building on the work of Shinkai's group, Norrild's group sought to create dyes that were both specific for the glucose molecule relative to other saccharides, and capable of binding glucose at neutral pH. Eggert et al, J.Org. Chem., 64, 3846-3852, 1999. To bind glucose at neutral pH, the boronic acid must have a $pK_a \leq 7$. Devising such a boronic acid sensor dye proved to be a major problem in that most of the dyes proposed up to that point had pK_a in the 8 to 10 range.

[0008] Norrild and co-workers chose 3-pyridineboronic acid for its especially low pK_a , and produced a bis-boronic acid comprising two 3-pyridineboronic acid moieties grafted onto an anthracene moiety. The resulting "Norrild" dyes (Fig. 1B) possessed the requisite low pK_a values and water solubility with a structurally optimized design for selective glucose binding. These dyes were reported to possess a selective fluorescence response to glucose compared to fructose and galactose.

[0009] Both the Shinkai and Norrild type dyes are solution-based systems. The solution-based system affords great freedom for the intramolecular changes that signal saccharide binding. However, certain applications require a solid-phase dye. Immobilization will likely reduce molecular freedom and alter the electrochemistry. This will in turn affect the fluorescence of the molecule, and might diminish its utility. That is, immobilization can reduce the fluorescence intensity or reduce the fluorescent response in the physiological testing region.

[0010] Saccharide sensors within the art generally have one or more shortcomings. For example, known sensors are capable of producing a discernible signal in response to saccharide binding, but do not provide the desired specificity for glucose relative to other saccharides.

[0011] Additionally, the known saccharide sensors lack the desired quantitative response. That is, as the concentration of saccharide increases, fluorescence increases only modestly. Preferably, the slope of relative fluorescence intensity as a function of saccharide concentration is high, and remains high throughout the range of saccharide concentration that is of physiological significance. Sensors exhibiting high slope of intensity, as a function of concentration will produce a signal that is more reliable and more readily discernible thereby substantially reducing costs of production.

[0012] Further, the use of fluorescence as a detection or diagnostic device benefits from a significant Stokes' shift. The Stokes' shift derives from the empirical law that the emission wavelength of a fluorescent material is longer than that of the radiation used to excite fluorescence. If the Stokes' shift is small, the excitation and emission peaks are in

close proximity, and it is necessary to resort to sophisticated optics and filtering devices to distinguish the two. As the Stokes' shift increases, the wavelength of the excitation peak moves further away from emission peak, and the reliance on filters to distinguish the two is reduced. This again, facilitates a more economical device.

[0013] Attempts to improve the glucose specificity of boronic acid based saccharide sensors, and/or improve the fluorescence properties of the sensor, and/or immobilize those traditionally solution-based systems on polymeric substrates have met with only limited success. E.g., Arimori, S., et al, Chem. Commun., 2001, 1836-1837.

[0014] One of the principle objectives in devising a saccharide dye is to create a dye that demonstrates a steep slope for the curve of relative intensity versus saccharide concentration. Shinkai and Norrild have shown that it is possible to create saccharide dyes that, in a solution-based system, have that steep slope. Subsequent work, however, has shown that the covalent linkage of those dyes to a solid substrate can result in a substantial reduction in that slope. As yet, there is nothing within the art disclosing saccharide dyes covalently attached to solid-phase that do not suffer a substantial loss or elimination of that slope.

[0015] Some workers have attempted to extend the work of Shinkai and Norrild to achieving solid-phase construction, but fail to produce a system that can be used in direct blood contact, or in ex-vivo approaches, in which blood is circulated outside the body. WO 01/74968 A2 and WO 01/20334 A1. That work focuses on the use of an allegedly solid-phase saccharide dye of the Shinkai type to be inserted in a patient under the skin to measure saccharide in interstitial fluid spaces. See also U.S. Patent Nos. 6,002,954, and 6,011,984.

[0016] There is a need within the art for saccharide dyes that have high glucose specificity. Ideally, such high specificity glucose sensors will demonstrate improved fluorescence properties. There is also a need in the art for dyes that retain such specificity and fluorescence properties when immobilized by covalent attachment to a solid substrate.

[0017] Further, WO 02/054067 A2 and WO 02/057788 disclose sensors for medicine and science. The sensors may be suited to detect glucose.

Detailed Description of the Invention

[0019] The present invention relates to a compound according to claim 1, a sensor according to claim 7 and a method according to claim 8, 9, 11 and 12. Further beneficial developments are set forth in the dependent claims.

[0020] The present invention provides solid-phase saccharide dyes, and methods for making them. The present invention further provides devices incorporating those dyes. The devices include liquid conduits incorporating the solid-phase dyes of the instant invention for detecting and monitoring saccharide levels in a fluid. Exemplary fluids are blood, blood fractions, plasma, urine, and other biological fluids or extracts of biological components.

[0021] For purposes of the present invention, the term "saccharide dye" is used to refer to molecules capable of reversibly binding a saccharide such that the molecule exhibits a discernible physicochemical change associated with the binding and/or release of the saccharide. In preferred embodiments, the physicochemical change is readily discernible by spectroscopic methods, e.g., fluorescence, phosphorescence, colorimetric, etc. The physicochemical change can thus be monitored by changes in a signal molecule or moiety, e.g., a fluorophore or phosphorescent species.

[0022] The term "solid-phase saccharide dye" is used to refer to a saccharide dye that is covalently attached to a solid substrate or solid-phase material. Exemplary substrates are natural or synthetic organic polymers and inorganic substrates such as ceramics and glass.

[0023] Polymers known to be biocompatible are preferred. Polymers generally recognized as biocompatible include cellulose (e.g., Cuprophane), polystyrene, polyamide, polyethersulfone, polyethyleneglycol, polypropyleneglycol, polyvinyl alcohol, polysiloxane, nylon (e.g., Bionolle), and copolymers thereof. Particularly preferred are polymers known to be highly biocompatible, e.g., cellulose, polyethersulfone, polyethylene glycol, polypropylene glycol, and polyvinyl alcohol.

[0024] Also preferred are polymers having available functional groups that facilitate covalent attachment to a functionalized hydrocarbon linker arm on the glucose sensor. Preferred functional groups in the polymer substrate are hydroxyl, carboxyl, aldehyde, ketone, amine, amide, and cyano.

[0025] The solid-phase to which the saccharide dye is covalently attached can be fabricated in many different forms, e.g., films, sheets, pellets, flakes, granules, microparticles, microspheres, etc. The preferred physical shape and size of the solid-phase will be largely dependent on the end product.

[0026] In one embodiment, the saccharide dye is immobilized on a solid substrate. The solid substrate is contacted with a fluid under investigation. The fluid can be a gas, vapor, or liquid. Fluid contact can be achieved by any conventional means, e.g., fluid bed, column, or conduit. Preferably, the fluid is a liquid such as blood, a blood fraction, plasma, urine, etc. As the fluid contacts the saccharide dye on the solid substrate, the dye signals the presence or absence, and preferably the quantity, of the analyte, e.g., glucose. The signal can be detected by colorimetric or spectroscopic means. The signal can be fed to conventional devices for display as by real-time read-out or by recording and displaying cumulative results as by charts, tables, or graphs.

[0027] In another embodiment, the product is a conduit for monitoring saccharide levels, particularly glucose, in blood. The saccharide dye is immobilized on a polymeric substrate. The polymeric substrate is incorporated in a conduit such that the saccharide dye is in contact with the fluid flowing through the conduit. The conduit can be incorporated into an in-line flow path for blood or some other biological fluid, *ex-vivo* or *in-vivo*. The dye is scanned or monitored to detect the level of analyte in the blood or other biological fluid.

[0028] The saccharide dye includes an aromatic polycyclic fluorophore, which is an acetyl-substituted anthracene. The dye can be attached to a solid-phase via linkages at nitrogen, the pyridine, or aromatic rings of fluorophore in the manner shown in Fig. 2.

[0029] The fluorescent property of a dye, such as excitation and emission wavelength, depends on the fluorophore, particularly the arrangement of the aromatic rings and the substitution on the rings. Elongation of aromatic conjugated double bond system, or introduction of halogen, acyl, alkyloxy, nitro, carboxylic acid, or carboxylic acid ester into the rings can improve the fluorescent property of a dye, and can effect a red shift or Stokes' shift. For example, our results show that the use of pyrene as a fluorophore for a Shinkai-type dye, or acetyl substitution of anthracene for a Shinkai-type dye, brought greater fluorescence (relative intensity) than an original or soluble Shinkai dye. These improvements give rise to increased sensitivity and accuracy in sensor performance.

[0030] More particularly, the manipulations described herein afford solid-phase saccharide dyes wherein the excitation-emission differential of the conjugated dye is about 40 nm or greater. As used herein, the term conjugated dye means a saccharide dye wherein the saccharide binding portion of the dye is occupied by a saccharide such that a signal is effected. In the case of a fluorescent dye, the conjugated dye will fluoresce indicating the presence of saccharide. Preferred solid-phase saccharide dyes of the present invention have an excitation-emission differential upon saccharide conjugation of about 45 nm or greater. Particularly preferred solid-phase saccharide dyes of the present invention have an excitation-emission differential upon conjugation of about 70 nm or greater.

[0031] Additionally, the solid-phase saccharide dyes of the present invention have increased fluorescence upon saccharide binding. Preferred embodiments have relative intensity across the physiologic range of about 1.5 or greater. For purposes of the present invention, the physiological range of glucose is from about 50 to about 500 mg/dl in blood, blood

fractions, or plasma. More preferred embodiments are capable of exhibiting relative intensity of about 2.0 or greater across the physiological range of glucose.

[0032] With reference to Figure 2, both mono(benzene boronic acid) and bis(benzene boronic acid) are useful saccharide sensing molecules that can be immobilized on a substrate. The saccharide binding and signal portions of the molecule are bound to the solid-phase by means of linker arms. The linker arms and non-linker substituents are saturated or unsaturated hydrocarbons that can be otherwise functionalized. The hydrocarbon chain can be branched or straight chain, and the length can vary quite extensively. The chain length is

[0033] C₃₀ or fewer. The functional groups can be maintained or protected for covalent attachment of the solid-phase and the dye. Alternatively, other functional groups can be employed for derivatizing the solid-phase and/or the dye prior to covalent attachment of the two.

[0034] Although the linker arms and non-linker substituents are described herein as hydrocarbon chains, as used herein the term includes functionalized hydrocarbons and includes at least alkyl, alkenyl, alkynyl, aldehydes, ketones, ethers, esters, amines, amides, carboxyl, halo, aryl, acyl, and like moieties. The various functional groups can occur in combination within a hydrocarbon linker arm, and can be internal to the hydrocarbon chain or at or about its terminus. The linker arm and non-linker hydrocarbons of the present invention can be straight-chain alkyl groups, or they can be functionalized or branched at various points along the hydrocarbon chain.

[0035] Preferably, a hydrocarbon of a linker arm is an alkyl, an amine, an amide, a ketone, an ether, an ester, and/or a combination thereof.

[0036] Preferred embodiments of the present invention include compounds of Formula 1:

Formula 1

[0037] According to Formula 1, at least one or more of R₁, R₂, and R₃ are linker arms for covalent attachment to solid-phase; and the remaining groups are non-linker substituents selected from among hydrogen, and saturated and unsaturated hydrocarbons that can be further activated with various functional groups. The hydrocarbon chain length of a non-linker substituent R₁, R₂, or R₃ can also vary, but will likewise be C₂₀ or fewer.

[0038] The substituents R₄, R₅, R₆, and R₇ are selected from the group consisting of hydrogen, alkyl, alkenyl, aryl, arylalkyl, substituted alkyl, acyl, alkyloxy, and halogen. The substituents R₄ and R₅, and R₆ and R₇ together can form condensed aromatic rings such as naphthalene, anthracene, and the like. In preferred embodiments, the bis-boronic acid compounds are symmetric around Q and comprise an aromatic ring or fused polycyclic aromatic ring.

[0039] Q is the signaling moiety that provides a detectable signal for monitoring saccharide binding and/or release.

[0040] Q is a fused polycyclic aromatic fluorophore, Q is a fluorophoric species comprising acetylated anthracene.

[0041] Other embodiments of the present invention are illustrated in Fig. 2, wherein one or more of the linker arms is selected from the group consisting of: -X-Y, -X-O-Y, -X-NH-Y, -X-N=Y, -X-NR-Y, X-CO-Y, -X-COO-Y, -X-OCO-Y, -X-NHCO-Y, -X-CONH-Y, -X-N=C(O-Y)₂, -X-NHCH(NH₂)-O-Y, -X-S-Y, -X-S-S-Y, -X-SO₂NH-Y and -X-NHSO₂-Y; wherein R is alkyl, alkenyl, aryl, arylalkyl or acyl; X is a saturated or an unsaturated hydrocarbon chain; Y is a solid-phase formed from a biocompatible polymer such as cellulose, polystyrene, polyamide, polyethersulfone, polyethyleneglycol, polypropyleneglycol, polyvinylalcohol and polysiloxane.

[0042] In preferred embodiments, R₁ and R₂ are the aforementioned linker arms formed of hydrocarbons of varying lengths. These two linker arms can be the same or different, although for ease of synthesis, they will often be the same.

[0043] In an intermediate stage, i.e., before the dye compound is covalently linked to the solid support, the dye compound is modified to include at least one functional group, e.g., carboxyl, hydroxyl, amino, cyano, or halogen substituent, to facilitate covalent attachment to the solid-phase. Alternatively, the linker arm can be first attached to the solid-phase or the dye compound. Alternatively, both the dye compound and the solid-phase can be derivatized with the covalent attachment be formed somewhere in between the two.

[0044] Similarly, other preferred embodiments are those wherein R₃ is a single linker arm that is covalently bound to Q on one end and a solid support on another. As above, the R₃ linker is preferably a saturated or unsaturated hydrocarbon chain that can be otherwise functionalized. As above, the length of the hydrocarbon chain can vary quite extensively, but will be C₃₀ or fewer. The hydrocarbons can be straight-chain alkyl groups, or they can be functionalized or branched at various points along the hydrocarbon chain. As above, the linker arm will preferably be functionalized as by a carboxyl, hydroxyl, amino, cyano, or halogen substituent to permit covalent attachment to a solid-phase material.

[0045] The R_3 linker arm can be covalently bound to the fluorophore, chromophore, or phosphorescent portion of the molecule at various locations. Preferably, it will be positioned where it will least interfere with the boronic acid substituents.

[0046] Where R_3 is the sole linker arm, R_1 and R_2 are preferably lower alkyl substituents. As used herein, the term lower alkyl means C_{1-12} .

[0047] Embodiments of the present invention include compounds of Formula 1 where: Q is a fluorophore, chromophore, or a phosphorescent or luminescent moiety; R_1 , R_2 , and R_3 are independently selected from the group consisting of a linker arm and a non-linking substituent; and R_4 , R_5 , R_6 , and R_7 are the same or different and are selected from the group consisting of hydrogen, alkyl, alkenyl, aryl, arylalkyl, substituted alkyl, acyl, alkyloxy, and halogen. Together, the substituents R_4 and R_5 , and R_6 and R_7 , respectively, can form condensed aromatic rings such as naphthalene, anthracene, and the like. As described above, a linker arm is a saturated or unsaturated hydrocarbon that can be derivatized with other functional groups, is C_{30} or fewer, and is covalently bound to a solid-phase material. A non-linking substituent is hydrogen or a saturated or unsaturated hydrocarbon of C_{20} or fewer and optionally further derivatized with other functional groups.

[0048] The biocompatible polymer can be a homopolymer or it can be a copolymer of two or more polymers. A dye can be covalently attached to an existing polymer, or the dye-polymer complex can be formed by a reaction between reactive monomers and a functional group on one or more linker arms of the dye.

[0049] The immobilized solid-phase dye can be built into a variety of sensor products, e.g., vessel, conduit, or bed. The solid-phase dye can be fixed in a product by conventional mechanical or chemical means. For example, the polymeric solid-phase portion of the solid-phase-dye complex can be affixed to a structural material such as a metal, glass, or polymer portion that forms a housing, vessel, conduit, or the like and through which the fluid under investigation is passed. Depending upon the choice of materials, these parts can be glued, fused, coextruded, cast, molded, or otherwise combined as by mechanical means, e.g., snaps, screws, slide-mounts, etc.

[0050] Further, the present invention is versatile in that the dye can be covalently linked to the solid-phase material before or after the solid-phase material is fabricated into the overall component product or a subcomponent of the product.

[0051] Relating to the preservation method of the sensor, the solution contacting the sensor may contain at least one polyol. A polyol-containing solution can be used to protect the sensor device during sterilization and storage.

EXAMPLES

1. *Shinkai Mono-phenylboronate / Single-arm type*

[0052] The dye designated PZ-33, its synthesis, and a means for immobilizing it to a Cuprophan substrate are illustrated in Figure 4.

[0053] PZ-33 is made with a linker arm attached to the nitrogen bridge between the benzene moiety and the anthracene moiety. The soluble dye senses saccharide over the physiologic range, but is somewhat sensitive to pH and ionic strength. The dye, both in solid-phase and soluble form, has limited stability when exposed to sterilization, high humidity, and high temperature.

[0054] When attached to a regenerated cellulose film (Cuprophan) via the linker arm, the dye retained saccharide sensitivity. However, the slope was less than the corresponding molecule in solution. The time response for binding glucose was very fast, less than a minute, but release was very slow. Sensitivity to shelf life and sterilization forces appears similar to soluble molecule.

[0055] An analogous compound (G47) with a pyrene fluorophore was also synthesized. The dye (G47) with a single spacer or linker arm was synthesized and then immobilized on a regenerated cellulose film (Cuprophan). Figure 5. The glucose response curve for the resulting sensor is shown in Figure 6.

2. *Shinkai bis-phenylboronate / Double-arm type*

[0056] These dyes are made with two linker arms attached to the nitrogen bridges between the benzene moiety and the anthracene moiety. Figure 7.

[0057] Dye with amino-terminated arms is synthesized from halomethylantracene, phenyl boronic acid, and mono protected alkyldiamine as linker arm moiety. Dye with carboxyl-terminated arms is synthesized using amino acid t-butyl ester as linker arm.

[0058] Glucose response of these dyes is greatly improved compared to the Shinkai mono-phenylboronate single-arm type dyes. Immobilization of these dyes is illustrated in Figures 8 - 10.

[0059] Glucose response curves of some of these sensors were better than the mono-phenyl boronate/single-arm type. Figure 11.

[0060] Solid-phase is not restricted to regenerated cellulose. For example, bis-phenyl boronate/double-arm type dye can be effectively immobilized by covalent attachment to activated nylon membranes such as Ultrabind^R or Biotyne^R.

(Pall Corp.). **Figure 12.** These immobilized saccharide sensor membranes had good glucose response.

[0061] The distance between dye and solid-phase can be controlled by using different length of spacers. This distance affects the reactivity of dye with saccharide on solid-phase. The use of polypropyleneglycol (PPG) as a spacer is illustrated in **Figure 13.**

[0062] The dye can be built into polymers as shown in **Figure 14.** Isocyanate terminated PPG was labeled with the dye, then cross linked by ethylenediamine, finally dye immobilized polymer was formed.

[0063] As an alternate method, amino terminated PPG was cross linked by isocyanate terminated cross linker, labeled with the dye, then the reaction was terminated by the addition of ethylenediamine. One advantage of this latter method is that solid-phase can be molded in any shape or form. The formed dye-polymer complex can be shaped into film, membrane, or shaped particles, or it can be applied to a sensor well or fiber tip by inpour or dabbing. Dye-polymer complexes formed by this method had good glucose response. **Figure 15.**

3. Shinkai bis-phenylboronate / Single-arm type

[0064] This class of dye has a single arm attachment of bis-phenylboronate dye. The dye has one linker arm covalently bonded directly to an aromatic ring of a fluorophore. In one embodiment, the dye has an available carboxyl group through which covalent immobilization is achieved. Anthracene carboxylic acid was derived from acetyl anthracene. The carboxyl group of the dye was attached to an amino activated solid-phase by condensation reaction using carbodiimide. **Figure 16.** This Single-Arm Fluorophore Linked Sensor was immobilized on a membrane and demonstrated favorable fluorescent property as shown in **Figure 17.** The glucose response curve of the Single-Arm Fluorophore Linked Sensor immobilized on a membrane is shown in **Figure 18.**

4. Improvement of fluorescent property (Example of the invention)

[0065] Introduction of an acyl group on the anthracene fluorophore improved the fluorescent property of the immobilized dye. The acetyl group was added to a substituted anthracene by a Friedel-Crafts reaction. Subsequent steps produced a bis-phenyl boronate type dye with two amino-terminated arms in the same manner as mentioned above. Immobilization via the amino-terminated linker arms to Cuprophan was carried out by a cyanogen-bromide activation method. **Figure 19.**

[0066] The resulting immobilized sensor had a better fluorescent property than the corresponding sensor without the acetyl group. The excitation and emission peaks were shifted to longer wavelengths and greater Stoke's shift. Immobilized sensor compounds having an emission peak of about 500 nm and an excitation peak below about 400 nm are suitable for an optical detection system, considering the properties of currently commercially available LEDs, optical filters, or photo detectors. **Figure 20.**

[0067] This sensor also gave a good glucose curve over the physiologic range in blood. **Figure 21.**

Claims

1. A compound of the formula:

where:

R_1 , R_2 , and R_3 are independently selected from the group consisting of linker arms and non-linker substituents; where the linker arm is a saturated or unsaturated, substituted or unsubstituted, hydrocarbon of C_{30} or fewer, and is covalently bonded to a solid-phase material; where the non-linker substituent is hydrogen, or a saturated or unsaturated, substituted or unsubstituted, hydrocarbon of C_{20} or fewer; and R_4 , R_5 , R_6 , and R_7 are the same or different, and are selected from the group consisting of hydrogen, alkyl, alkenyl, aryl, arylalkyl, substituted alkyl, acyl, alkyloxy, and halogen, wherein Q is an acetyl-substituted anthracene.

2. The compound of claim 1, wherein Q is:

3. The compound of claim 1, which is represented by the formula:

wherein:

R_1 and R_2 are the same and are selected from the group consisting of carboxyalkyl and alkylamin substituents, and are covalently bound to a solid-phase support material; and
 R_3 is selected from the group consisting of hydrogen, halogen, alkyl, acyl, alkyloxy, nitro, carboxylic acid, and carboxylic acid ester; and
 $\text{R}_4, \text{R}_5, \text{R}_6$, and R_7 are the same or different, and are selected from the group consisting of hydrogen, alkyl, alkenyl, aryl, arylalkyl, acyl, alkyloxy, and halogen.

4. The compound of claim 3, wherein R_1 and R_2 are both $-\text{CH}_2-\text{C(O)}-\text{OH}$ or $-\text{C}_6\text{H}_{12}-\text{NH}_2$.

5. The compound of claim 1, which is represented by the formula:

where:

Q is anthracene;
 R_1 and R_2 are $\text{C}_1\text{-C}_{12}$ hydrocarbons covalently bonded to a solid-phase material;
and R_3 is acetyl; and
 R_4 and R_5 , and R_6 and R_7 are either all H, or the two pairs respectively form a condensed aromatic ring structure.

6. The compound of claim 1, which is represented by the formula:

wherein:

Q is an acetyl-substituted anthracene;

R₁ and R₂ are non-linker hydrocarbons of C₁-C₁₂;

R₃ is an amide containing hydrocarbon linker arm covalently bonded to a polymeric solid-phase support; and

R₄ and R₅, and R₆ and R₇ are either all H, or the two pairs respectively form a condensed aromatic ring structure.

7. A sensor for detecting the concentration of saccharide in a biological fluid comprising a fluid conduit wherein a compound of claim 1 is covalently attached to an interior wall of the conduit such that the compound is in contact with fluid flowing through the conduit.

8. A method for detecting the concentration of saccharide in a biological fluid comprising contacting a biological fluid with an immobilized compound of claim 1, and measuring the relative intensity of fluorescence of the compound.

9. A method for immobilizing a compound of claim 1 comprising reacting a compound of the formula:

where:

R₁, R₂, and R₃ are independently selected from the group consisting of: hydrogen, amino-terminated hydrocarbons of C₃₀ or fewer, and a hydrocarbon of C₃₀ or fewer, such that at least one of R₁, R₂, and R₃ is a amino-terminated hydrocarbon;

R₄, R₅, R₆, and R₇ are the same or different, and are selected from the group consisting of hydrogen, alkyl, alkenyl, aryl, arylalkyl, acyl, alkyloxy, and halogen; and

reacting the amino-terminated hydrocarbon with a polymer activated with a functional group selected from the group consisting of carboxyl, carbonyl, cyanogenbromide, epoxy, and isocyanate.

10. The method of claim 9, wherein the activated polymer is crosslinked with ethylenediamine.

11. A method for immobilizing a compound of claim 1 comprising reacting a compound of the formula:

where:

R_1 , R_2 , and R_3 are independently selected from the group consisting of: hydrogen, carboxyl-terminated hydrocarbons of C_{30} or fewer, and a hydrocarbon of C_{30} or fewer, such that at least one of R_1 , R_2 , and R_3 is a carboxyl-terminated hydrocarbon;

R_4 , R_5 , R_6 , and R_7 are the same or different, and are selected from the group consisting of hydrogen, alkyl, alkenyl, aryl, arylalkyl, acyl, alkyloxy, and halogen; and

reacting the carboxyl-terminated hydrocarbon with an amino-activated solid-phase polymer.

12. A method for immobilizing a compound of claim 1 comprising reacting a compound of the formula:

where:

R_1 , R_2 , and R_3 are independently selected from the group consisting of: hydrogen, amino-terminated hydrocarbons of C_{30} or fewer, and a hydrocarbon of C_{30} or fewer, such that at least one of R_1 , R_2 , and R_3 is an amino-terminated hydrocarbon;

R_4 , R_5 , R_6 , and R_7 are the same or different, and are selected from the group consisting of hydrogen, alkyl, alkenyl, aryl, arylalkyl, acyl, alkyloxy, and halogen; and

reacting the amino-terminated hydrocarbon with isocyanate-activated polypropylene glycol; and cross-linking the polypropylene glycol with ethylene diamine.

Patentansprüche

1. Verbindung der Formel:

wobei:

R_1 , R_2 und R_3 unabhängig ausgewählt sind aus der Gruppe bestehend aus Linker-Armen und nicht-Linker-Substituenten;

wobei der Linker-Arm ein gesättigter oder ungesättigter, substituierter oder unsubstituierter Kohlenwasserstoff von C_{30} oder geringer ist und kovalent an ein Festphasenmaterial gebunden ist;

wobei der nicht-Linker-Substituent Wasserstoff oder ein gesättigter oder ungesättigter, substituierter oder unsubstituierter Kohlenwasserstoff von C_{20} oder geringer ist; und R_4 , R_5 , R_6 und R_7 gleich oder unterschiedlich sind und ausgewählt sind aus der Gruppe bestehend aus Wasserstoff, Alkyl, Alkenyl, Aryl, Arylalkyl, substituiertem Alkyl, Acyl, Alkyloxy und Halogen,

wobei Q ein Acyl-substituiertes Anthracen ist.

2. Verbindung nach Anspruch 1, wobei Q ist:

3. Verbindung nach Anspruch 1, welche durch die Formel dargestellt ist:

wobei:

R_1 und R_2 gleich oder unterschiedlich sind und aus der Gruppe bestehend aus Carboxyalkyl- und Alkylamin-substituenten ausgewählt sind und kovalent an ein Festphasenträgermaterial gebunden sind; und R_3 ausgewählt ist aus der Gruppe bestehend aus Wasserstoff, Halogen, Alkyl, Acyl, Alkyloxy, Nitro, Carbonsäure und Carbonsäureester; und

R_4 , R_5 , R_6 und R_7 gleich oder unterschiedlich sind und ausgewählt sind aus der Gruppe bestehend aus Wasserstoff, Alkyl, Alkenyl, Aryl, Arylalkyl, Acyl, Alkyloxy und Halogen.

4. Verbindung nach Anspruch 3, wobei R_1 und R_2 beide $-\text{CH}_2-\text{C}(\text{O})-\text{OH}$ oder $-\text{C}_6\text{H}_{12}-\text{NH}_2$ sind.

5. Verbindung nach Anspruch 1, welche durch die Formel dargestellt ist:

wobei:

Q Anthracen ist;

R_1 und R_2 $\text{C}_1\text{-C}_{12}$ Kohlenwasserstoffe sind, die kovalent an ein Festphasenmaterial gebunden sind; und R_3 Acetyl ist; und

R_4 und R_5 , und R_6 und R_7 entweder alle Wasserstoff sind oder die beiden Paare jeweils eine kondensierte aromatische Ringstruktur bilden.

6. Verbindung nach Anspruch 1, welche durch die Formel dargestellt ist:

wobei:

Q ein Acetyl-substituiertes Anthracen ist;

R₁ und R₂ nicht-Linker Kohlenwasserstoffe von C₁-C₁₂ sind;

R₃ ein Amid ist, das einen Kohlenwasserstoff-Linker-Arm enthält, der kovalent an einen polymeren Festphasen-träger gebunden ist; und

R₄ und R₅, und R₆ und R₇ entweder alle Wasserstoff sind oder die beiden Paare jeweils eine kondensierte aromatische Ringstruktur bilden.

7. Sensor zum Detektieren der Konzentration eines Saccharids in einem biologischen Fluid, umfassend eine Fluidleitung, wobei eine Verbindung nach Anspruch 1 kovalent an eine Innenwand der Leitung angebracht ist, so dass die Verbindung in Kontakt mit durch die Leitung strömendem Fluid steht.

8. Verfahren zum Detektieren der Konzentration eines Saccharids in einem biologischen Fluid, umfassend das in Kontakt bringen eines biologischen Fluides mit einer immobilisierten Verbindung nach Anspruch 1, und Messen der relativen Intensivität der Fluoreszenz der Verbindung.

9. Verfahren zum Immobilisieren einer Verbindung nach Anspruch 1, umfassend das Reagieren lassen einer Verbindung der Formel:

wobei:

R₁, R₂ und R₃ unabhängig ausgewählt sind aus der Gruppe bestehend aus: Wasserstoff, Amino-terminierten Kohlenwasserstoffen mit C₃₀ oder geringer, und einem Kohlenwasserstoff von C₃₀ oder geringer, so dass zumindest eines aus R₁, R₂ und R₃ ein Amino-terminierter Kohlenwasserstoff ist;

R₄, R₅, R₆ und R₇ gleich oder unterschiedlich sind und ausgewählt sind aus der Gruppe bestehend aus Wasserstoff, Alkyl, Alkenyl, Aryl, Arylalkyl, Acyl, Alkyloxy und Halogen; und

reagieren lassen des Amino-terminierten Kohlenwasserstoffs mit einem Polymer, das aktiviert ist mit einer funktionellen Gruppe, ausgewählt aus der Gruppe bestehend aus Carboxyl, Carbonyl, Cyanogenbromid, Epoxy und Isocyanat.

10. Verfahren nach Anspruch 9, wobei das aktivierte Polymer mit Ethylendiamin vernetzt ist.

11. Verfahren zum Immobilisieren einer Verbindung nach Anspruch 1, umfassend das Reagieren lassen einer Verbindung der Formel:

wobei:

R_1 , R_2 und R_3 unabhängig ausgewählt sind aus der Gruppe bestehend aus: Wasserstoff, Carboxyl-terminierten Kohlenwasserstoffen von C_{30} oder geringer, und einem Kohlenwasserstoff von C_{30} oder geringer, so dass zumindest eines aus R_1 , R_2 und R_3 ein Carboxyl-terminierter Kohlenwasserstoff ist;
 R_4 , R_5 , R_6 und R_7 gleich oder unterschiedlich sind und ausgewählt aus der Gruppe bestehend aus Wasserstoff, Alkyl, Alkenyl, Aryl, Arylalkyl, Acyl, Alkyloxy und Halogen; und
 reagieren lassen des Carboxyl-terminierten Kohlenwasserstoffs mit einem Amino-aktivierten Festphasenpolymer.

12. Verfahren zum Immobilisieren einer Verbindung nach Anspruch 1, umfassend das Regieren lassen einer Verbindung der Formel:

wobei:

R_1 , R_2 und R_3 unabhängig ausgewählt sind aus der Gruppe bestehend aus: Wasserstoff, Amino-terminierten Kohlenwasserstoffen von C_{30} oder geringer, und einem Kohlenwasserstoff von C_{30} oder geringer, so dass zumindest eines aus R_1 , R_2 und R_3 ein Amino-terminierter Kohlenwasserstoff ist;
 R_4 , R_5 , R_6 und R_7 gleich oder unterschiedlich sind und ausgewählt sind aus der Gruppe bestehend aus Wasserstoff, Alkyl, Alkenyl, Aryl, Arylalkyl, Acyl, Alkyloxy und Halogen; und
 reagieren lassen des Amino-terminierten Kohlenwasserstoffs mit Isocyanat-aktiviertem Polypropylenglycol; und
 vernetzen des Polypropylenglycols mit Ethylendiamin.

Revendications

1. Composé de formule :

où :

R_1 , R_2 , et R_3 sont indépendamment choisis dans le groupe constitué par des bras lieurs et des substituants non-lieurs ;

où le bras lieur est un hydrocarbure saturé ou insaturé, substitué ou non substitué, de C_{30} ou moins, et est lié par covalence à un matériau de phase solide ;

où le substituant non-lieur est un hydrogène, ou un hydrocarbure saturé ou insaturé, substitué ou non substitué, de C_{20} ou moins ; et

R_4 , R_5 , R_6 , et R_7 sont identiques ou différents, et sont choisis dans le groupe constitué par un hydrogène, alkyle, alcényle, aryle, arylalkyle, alkyle substitué, acyle, alkyloxy et halogène, dans lequel Q est un anthracène substitué par un acétyle.

2. Composé selon la revendication 1, dans lequel Q est :

3. Composé selon la revendication 1, qui est représenté par la formule :

où :

R_1 et R_2 sont identiques et sont choisis dans le groupe constitué par des substituants carboxyalkyle et alkylamine, et sont liés par covalence à un matériau support de phase solide ; et

R_3 est choisi dans le groupe constitué par un hydrogène, halogène, alkyle, acyle, alkyloxy, nitro, acide carboxylique et ester d'acide carboxylique ; et

R_4 , R_5 , R_6 , et R_7 sont identiques ou différents, et sont choisis dans le groupe constitué par un hydrogène, alkyle, alcényle, aryle, arylalkyle, acyle, alkyloxy et halogène.

4. Composé selon la revendication 3, dans lequel R_1 et R_2 sont tous deux $-CH_2-C(O)-OH$ ou $-C_6H_{12}-NH_2$.

5. Composé selon la revendication 1, qui est représenté par la formule :

où :

Q est un anthracène ;

R₁ et R₂ sont des hydrocarbures en C₁-C₁₂ liés par covalence à un matériau de phase solide ;
et R₃ est un acétyle ; et

R₄ et R₅, et R₆ et R₇ sont soit tous un H, soit les deux paires forment respectivement une structure de cycle aromatique condensé.

6. Composé selon la revendication 1, qui est représenté par la formule :

dans laquelle :

Q est un anthracène substitué par un acétyle ;

R₁ et R₂ sont des hydrocarbures non-lieurs de C₁-C₁₂ ;

R₃ est un bras lieur hydrocarboné contenant de l'aramide lié par covalence à un support de phase solide polymère ; et

R₄ et R₅, et R₆ et R₇ sont soit tous un H, soit les deux paires forment respectivement une structure de cycle aromatique condensé.

7. Capteur pour détecter la concentration en saccharide dans un liquide biologique comprenant un conduit de liquide dans lequel un composé selon la revendication 1 est attaché par covalence à une paroi intérieure du conduit de sorte que le composé est en contact avec le liquide s'écoulant à travers le conduit.

8. Procédé pour détecter la concentration en saccharide dans un liquide biologique comprenant la mise en contact d'un liquide biologique avec un composé immobilisé selon la revendication 1, et la mesure de l'intensité de fluorescence relative du composé.

9. Procédé pour immobiliser un composé selon la revendication 1, comprenant la réaction d'un composé de formule :

où :

R_1 , R_2 , et R_3 sont indépendamment choisis dans le groupe constitué par : un hydrogène, des hydrocarbures à terminaison amino de C_{30} ou moins, et un hydrocarbure de C_{30} ou moins, de sorte qu'au moins l'un de R_1 , R_2 , et R_3 est un hydrocarbure à terminaison amino ;
 R_4 , R_5 , R_6 , et R_7 sont identiques ou différents, et sont choisis dans le groupe constitué par un hydrogène, alkyle, alcényle, aryle, arylalkyle, acyle, alkyloxy et halogène ; et
 la réaction de l'hydrocarbure à terminaison amino avec un polymère activé ayant un groupe fonctionnel choisi dans le groupe constitué par un carboxyle, carbonyle, bromure de cyanogène, époxy et isocyanate.

10. Procédé selon la revendication 9, dans lequel le polymère activé est réticulé avec de l'éthylènediamine.

11. Procédé pour immobiliser un composé selon la revendication 1, comprenant la réaction d'un composé de formule :

où :

R_1 , R_2 , et R_3 sont indépendamment choisis dans le groupe constitué par : un hydrogène, des hydrocarbures à terminaison amino de C_{30} ou moins, et un hydrocarbure de C_{30} ou moins, de sorte qu'au moins l'un de R_1 , R_2 , et R_3 est un hydrocarbure à terminaison carboxyle ;
 R_4 , R_5 , R_6 , et R_7 sont identiques ou différents, et sont choisis dans le groupe constitué par un hydrogène, alkyle, alcényle, aryle, arylalkyle, acyle, alkyloxy et halogène ; et
 la réaction de l'hydrocarbure à terminaison carboxyle avec un polymère de phase solide amino-activé.

12. Procédé pour immobiliser un composé selon la revendication 1, comprenant la réaction d'un composé de formule :

où :

R₁, R₂, et R₃ sont indépendamment choisis dans le groupe constitué par : un hydrogène, des hydrocarbures à terminaison amino de C₃₀ ou moins, et un hydrocarbure de C₃₀ ou moins, de sorte qu'au moins l'un de R₁, R₂, et R₃ est un hydrocarbure à terminaison amino ;
 R₄, R₅, R₆, et R₇ sont identiques ou différents, et sont choisis dans le groupe constitué par un hydrogène, alkyle, alcényle, aryle, arylalkyle, acyle, alkyloxy et halogène ; et
 la réaction de l'hydrocarbure à terminaison amino avec du polypropylène glycol activé par de l'isocyanate ; et
 la réticulation du polypropylène glycol avec de l'éthylène diamine.

摘要(译)

本发明提供固相糖类染料。染料是与固体基质共价键合的二硼酸。染料选择性地与糖类，特别是葡萄糖结合，并记录信号。信号与糖的量成比例。因此，本发明的染料可用于测量和监测糖水平，特别是在诸如血液的生物流体中。
