[0001] This application claims the benefit of U.S. Provisional Application No. 60/944,484, filed on Jun. 15, 2007, which is incorporated by reference herein in its entirety. This invention was made with government support under AI067501 and AI050029 awarded by the National Institutes of Health. The Government has certain rights in the invention.

I. BACKGROUND

[0002] Current methods of assessing antibody mediated vaccine responses are to measure rises in pre and post exposure antibody titers (i.e., neutralizing antibodies via ELISA). Though effective, the current methods necessitate a waiting period of approximately 30 days post antigen exposure before an assessment for efficacy can be made.

II. SUMMARY

[0003] Disclosed are methods and kits related to assessing the level or presence or antibody secreting cells in a subject following antigen exposure.

[0004] In another embodiment, disclosed are methods of assessing the efficacy of a vaccine in a subject comprising obtaining peripheral blood mononuclear cells (PBMC) from the subject between 5 and 15 days following administration of the vaccine, measuring the number of antibody secreting cells (ASC) in the PBMC, and comparing the number of ASC to a standard, wherein more ASC in the PBMC relative to a standard indicates an efficacious vaccine.

[0005] In another embodiment disclosed are methods of assessing the need of the administration of a booster immunization in a subject comprising obtaining peripheral blood mononuclear cells (PBMC) from the subject between 5 and 15 days following administration of a vaccine, measuring the number of antibody secreting cells (ASC) in the PBMC, and comparing the number of ASC to a standard, wherein fewer ASC in the PBMC relative to a standard indicates the need for an immunization boost.

III. BRIEF DESCRIPTION OF THE DRAWINGS

[0006] The accompanying drawings, which are incorporated in and constitute a part of this specification, illustrate several embodiments and together with the description illustrate the disclosed compositions and methods.

[0007] FIG. 1 shows a comparison of fresh vs. frozen plasmablasts by flow cytometry and ASC ELISpots pre- and 7 day post-influenza vaccination.

[0008] FIG. 2 shows influenza-specific ASC from fresh PBMC Pre- and 7 day-post vaccination. P=one tailed paired T-test

[0009] FIG. 3 shows a comparison of ASC from fresh vs. frozen PBMC 7 day post-influenza vaccination. R=correlation coefficients.

[0010] FIG. 4 shows the kinetics of influenza-specific ASC (plasmablasts) in peripheral blood from 2 young healthy subjects. FIG. 4A shows a patient with prior influenza vaccination exposure through a history of annual influenza vaccinations. FIG. 4B shows a patient with no history of prior vaccination or infection.

[0011] FIG. 5 shows antigen-specific ASC ex vivo in the blood after antigen exposure is short-lived approximately from day 5-15 after a single antigen dose. Shown in FIG. 5 is a representative of the kinetics of one subject's ASC for total IgG, Hemagglutinins H1, H3, H7, trivalent influenza vaccine (TIV) from 2006 directly ex vivo from the blood pre and days post-TIV. Each circle represents wells coated with either total anti-human IgG, purified H1 (New Caledonia), H3 (H3 A/Wyoming, which is closely related to A/Wisconsin), H7 (an avian strain to function as a negative control), and TIV (TIV vaccine components are H1 A/New Caledonia/20/99, He A/Wisconsin/67/2005, and B/Malaysia/2506/2004). PBMC numbers 30,000 or 300,000 were added to each well as shown above and incubated for 18-20 hours. Cells were removed and biotinylated anti-human IgG (recognizing all 4 subclasses) was added and developed. The total IgG ASC frequencies can increase to 0.02-0.8% of the PBMC. The antigen-specific ASC frequencies of the total IgG can range from 20-60%.

[0012] FIG. 6 shows kinetics of 6 young healthy adult human subjects (subjects 3-8, panels A-F, respectively) receiving influenza vaccine.

[0013] FIG. 7 shows antigen-specific ASC ELISpots can further identify acute influenza infections of different influenza strains.

IV. DETAILED DESCRIPTION

[0014] Before the present compounds, compositions, articles, devices, and/or methods are disclosed and described, it is to be understood that they are not limited to specific synthetic methods or specific recombinant biotechnology methods unless otherwise specified, or to particular reagents unless otherwise specified, as such may, of course, vary. It is also to be understood that the terminology used herein is for the purpose of describing particular embodiments only and is not intended to be limiting.

Definitions

[0015] As used in the specification and the appended claims, the singular forms "a," "an" and "the" include plural referents unless the context clearly dictates otherwise. Thus, for example, reference to "a pharmaceutical carrier" includes mixtures of two or more such carriers, and the like.

[0016] Ranges can be expressed herein as from "about" one particular value, and/or to "about" another particular value. When such a range is expressed, another embodiment includes from the one particular value and/or to the other particular value. Similarly, when values are expressed as approximations, by use of the antecedent "about," it will be understood that the particular value forms another embodiment. It will be further understood that the endpoints of each of the ranges are significant both in relation to the other endpoint, and independently of the other endpoint. It is also understood that there are a number of values disclosed herein, and that each value is also herein disclosed as "about" that particular value in addition to the value itself. For example, if the value "10" is disclosed, then "about 10" is also disclosed. It is also understood that when a value is disclosed that "less than or equal to" the value, "greater than or equal to the value" and possible ranges between values are also disclosed, as appropriately understood by the skilled artisan. For example, if the value "10" is disclosed the "less than or equal to 10" as well as "greater than or equal to 10" is also disclosed. It is also

understood that the throughout the application, data is provided in a number of different formats, and that this data, represents endpoints and starting points, and ranges for any combination of the data points. For example, if a particular data point "10" and a particular data point 15 are disclosed, it is understood that greater than, greater than or equal to, less than, less than or equal to, and equal to 10 and 15 are considered disclosed as well as between 10 and 15. It is also understood that each unit between two particular units are also disclosed. For example, if 10 and 15 are disclosed, then 11, 12, 13, and 14 are also disclosed.

[0017] In this specification and in the claims which follow, reference will be made to a number of terms which shall be defined to have the following meanings:

[0018] "Optional" or "optionally" means that the subsequently described event or circumstance may or may not occur, and that the description includes instances where said event or circumstance occurs and instances where it does not.

[0019] Throughout this application, various publications are referenced. The disclosures of these publications in their entireties are hereby incorporated by reference into this application in order to more fully describe the state of the art to which this pertains. The references disclosed are also individually and specifically incorporated by reference herein for the material contained in them that is discussed in the sentence in which the reference is relied upon.

#### Methods of Use

[0020] Disclosed herein are methods of assessing the efficacy of a vaccine in a subject comprising obtaining peripheral blood mononuclear cells (PBMC) from the subject between 5 and 15 days following administration of the vaccine, measuring the number of antibody secreting cells (ASC) in the PBMC, and comparing the number of ASC to a standard, wherein more ASC in the PBMC relative to a standard indicates an efficacious vaccine. Also disclosed are methods of assessing the effectiveness of a therapy for an autoimmune disease comprising obtaining peripheral blood mononuclear cells (PBMC) from the subject and measuring the presence of antibody secreting cells (ASC) in the PBMC, wherein the absence of ASC indicates an effective therapy.

[0021] "Efficacy," "efficacious," or "sufficiency" mean the ability to function as intended. For example, an "efficacious" immune response is a response that is able to afford the subject an acceptable degree of immune protection from the immunizing antigen. Thus, the present methods disclose methods of assessing the ability of an immune response to provide immune protection against future antigenic encounter. Traditionally, such methods involve antigenic challenge. It is understood that the present methods provide an alternative means to achieve the goal of antigenic challenge and can be used separately or in conjunction with a challenge to determine efficacy or sufficiency.

[0022] Throughout this application the term "sufficient immune response" is used to describe an immune response of a large enough magnitude to provide an acceptable immune protection to the subject against future antigen encounter. It is understood that immune protection does not necessarily mean prevention of future antigenic encounter (e.g., infection), nor is it limited to a lack of any pathogenic symptoms. "Immune protection" means a prevention of the full onset of a pathogenic condition. Thus in one embodiment a "sufficient immune response" is a response that reduces the symptoms, magnitude, or duration of an infection or other disease con-

dition when compared with an appropriate control. The control can be a subject that is exposed to an antigen before or without a sufficient immune response.

[0023] It is understood herein that an "immune response" refers to any inflammatory, humoral, or cell-mediated response that occurs for the purpose of eliminating an antigen. Such responses can include, but are not limited to, antibody production, cytokine secretion, complement activity, and cytolytic activity. In one embodiment, the immune response is an antibody response.

[0024] By "effective amount" is meant a therapeutic amount needed to achieve the desired result or results, e.g., establishing an immune response that can confer immunological protection to the subject. It is understood that immunological protection includes but is not limited to prevention of subsequent infections; reduction of the effects or symptoms of subsequent infections or conditions; reduction in the duration of the infection or condition; lessening of severity of a disease or condition; or reduced antigenic load relative to non-treated controls.

[0025] The need for knowing the sufficiency of an immune response is directly related to the need to administer one or more subsequent vaccines to a subject with an insufficient response. Referred to as a booster immunization, these subsequent vaccine administrations elevate immune response to protective levels. Accordingly, disclosed herein are methods of assessing the need of the administration of a booster immunization in a subject comprising obtaining peripheral blood mononuclear cells (PBMC) from the subject between 5 and 15 days following administration of a vaccine, measuring the number of antibody secreting cells (ASC) in the PBMC, and comparing the number of ASC to a standard, wherein fewer ASC in the PBMC relative to a standard indicates the need for an immunization boost.

[0026] Disclosed herein are methods of determining antigen exposure in a subject comprising obtaining peripheral blood mononuclear cells (PBMC) from the subject and measuring the presence of antibody secreting cells (ASC) in the PBMC, wherein the presence of ASC indicates antigen exposure. It is understood and herein contemplated that the existence of antigen-specific ASC is indicative of an infection. Accordingly, the present methods of determining antigen exposure in a subject can be used to diagnose a subject with an infectious, autoimmune, or parasitic disease wherein the presence of antigen-specific ASC indicates a subject has the disease from which the antigen was derived. In the case of an autoimmune disease the antigen would be from the subject.

[0027] Similarly, the methods disclosed herein can be used to assess the immune response to an allergen. Current methods of determining allergic reactions include the "scratch test" and ELISAs. The scratch test is an assay where an abrasion is created on the subjects skin and a potential allergen applied directly to the abrasion. A qualitative assessment is then made to determine whether any observed inflammation is of a significant enough amount to be considered an allergic response. This assay is an uncomfortable process for the subject and prone to false positives as a strong response in one abrasion site can carry over to neighboring sites. By utilizing the ASC methods disclosed herein, a panel of allergens can be tested in vitro so less discomfort is created for the subject. Moreover, an exact quantification of the allergen specific ASC can be determined. Thus, rather than a qualitative assay based on perceived inflammation, the exact amount of IgE bearing ASC specific for the allergen can be quantified

creating no chance of a false positive. Accordingly, disclosed herein are methods of diagnosing the presence of an allergy in a subject comprising obtaining peripheral blood mononuclear cells (PBMC) from the subject and measuring the presence of antibody secreting cells (ASC) in the PBMC, wherein the presence of ASC indicates antigen exposure.

**[0028]** The methods disclosed herein comprise assessing the efficacy or sufficiency of an immune response to a selected antigen in a subject as well as diagnosing antigen exposure in a subject. The disclosed methods utilize tissue samples from the subject to provide the basis for assessment. Such tissue samples can include, but are not limited to, blood (including peripheral blood and peripheral blood mononuclear cells), tissue biopsy samples (e.g., spleen, liver, bone marrow, thymus, lung, kidney, brain, salivary glands, skin, lymph nodes, and intestinal tract), and specimens acquired by pulmonary lavage (e.g., bronchoalveolar lavage (BAL)). Thus it is understood that the tissue sample can be from both lymphoid and non-lymphoid tissue. Examples of non-lymphoid tissue include but are not limited to lung, liver, kidney, and gut. Lymphoid tissue includes both primary and secondary lymphoid organs such as the spleen, bone marrow, thymus, and lymph nodes.

**[0029]** The methods disclosed herein measure exposure, efficacy, effectiveness, or need for further treatment through the measure of the number of presence of antibody secreting cells (ASC). It is understood and herein contemplated that "antibody secreting cell" or "plasma cell" refers to any B lineage cell capable of secreting antibody including but not limited to plasmablasts, short-lived antibody secreting cells, long-lived plasma cell. It is further understood and specifically contemplated that the presence or number of such cells can be determined by any of the immunoassays disclosed herein, including but not limited to ELISPOT assay. It is further understood that where a ELISPOT assay is used to measure the presence or level of antibody secreting cells to a particular antigen, that ELISPOT assay can be antigen specific.

**[0030]** It is understood and herein contemplated that the disclosed methods can be performed with PBMCs obtained 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, or 15 days following vaccination. In one aspect the PBMC are obtained between 3 and 12 days following vaccination. In another aspect, the PBMC are obtained between 3 and 10 days following vaccination. In another aspect, the PBMC are obtained between 5 and 10 days following vaccination. In yet another aspect, the PBMC are obtained between 5 and 8 days following vaccination. Therefore, disclosed herein are methods of assessing the need of the administration of a booster immunization in a subject comprising obtaining peripheral blood mononuclear cells (PBMC) from the subject between 5 and 15 days following administration of a vaccine, measuring the number of antibody secreting cells (ASC) in the PBMC, and comparing the number of ASC to a standard, wherein fewer ASC in the PBMC relative to a standard indicates the need for an immunization boost.

**[0031]** "Antigen" means any native or foreign substance that is capable of eliciting an immune response. Preferably, the antigen will elicit an antibody, plasma cell, plasmablast, or B-cell response. Such antigens can include but are not limited to peptides and/or proteins from a subject, virus, bacteria, yeast, or parasite, including but not limited to toxins. Antigens can also include vaccines (e.g., peptides, proteins, killed pathogens, or attenuated pathogens administered in a

pharmaceutically acceptable carrier either prophylactically or therapeutically), bio-warfare agents, and native peptides, polypeptides, and proteins.

**[0032]** It is understood that the antigen can be a viral antigen. Viral antigens can include any peptide, polypeptide, or protein from a virus. Thus in one embodiment the antigen can be an antigen from a virus selected from the group consisting of Herpes Simplex virus-1, Herpes Simplex virus-2, Varicella-Zoster virus, Epstein-Barr virus, Cytomegalovirus, Human Herpes virus-6, Variola virus, Vesicular stomatitis virus, Hepatitis A virus, Hepatitis B virus, Hepatitis C virus, Hepatitis D virus, Hepatitis E virus, Rhinovirus, Coronavirus, Influenza virus A, Influenza virus B, Measles virus, Polyomavirus, Human Papillomavirus, Respiratory syncytial virus, Adenovirus, Coxsackie virus, Dengue virus, Mumps virus, Poliovirus, Rabies virus, Rous sarcoma virus, Reovirus, Yellow fever virus, Ebola virus, Marburg virus, Lassa fever virus, Eastern Equine Encephalitis virus, Japanese Encephalitis virus, St. Louis Encephalitis virus, Murray Valley fever virus, West Nile virus, Rift Valley fever virus, Rotavirus A, Rotavirus B, Rotavirus C, Sindbis virus, Simian Immunodeficiency virus, Human T-cell Leukemia virus type-1, Hantavirus, Rubella virus, Simian Immunodeficiency virus, Human Immunodeficiency virus type-1, and Human Immunodeficiency virus type-2.

**[0033]** In particular, it is understood that the viral antigen can be an antigen from Influenza-A. Therefore it is understood that the present methods include methods of assessing the efficacy or sufficiency of an immune response to an Influenza-A antigen. Preferably the Influenza-A antigen is an attenuated or killed strain of Influenza-A.

**[0034]** Also disclosed are methods wherein the antigen is a bacterial antigen. The antigen, for example, can be a peptide, polypeptide, or protein selected from the group of bacteria consisting of *M. tuberculosis*, *M. bovis*, *M. bovis* strain BCG, BCG substrains, *M. avium*, *M. intracellulare*, *M. africanum*, *M. kansasii*, *M. marinum*, *M. ulcerans*, *M. avium* subspecies *paratuberculosis*, *Nocardia asteroides*, other *Nocardia* species, *Legionella pneumophila*, other *Legionella* species, *Salmonella typhi*, other *Salmonella* species, *Shigella* species, *Yersinia pestis*, *Pasteurella haemolytica*, *Pasteurella multocida*, other *Pasteurella* species, *Actinobacillus pleuropneumoniae*, *Listeria monocytogenes*, *Listeria ivanovii*, *Brucella abortus*, other *Brucella* species, *Cowdria ruminantium*, *Chlamydia pneumoniae*, *Chlamydia trachomatis*, *Chlamydia psittaci*, *Coxiella burnetti*, other *Rickettsial* species, *Ehrlichia* species, *Staphylococcus aureus*, *Staphylococcus epidermidis*, *Streptococcus pneumoniae*, *Streptococcus pyogenes*, *Streptococcus agalactiae*, *Bacillus anthracis*, *Escherichia coli*, *Vibrio cholerae*, *Campylobacter* species, *Neisseria meningitidis*, *Neisseria gonorrhoea*, *Pseudomonas aeruginosa*, other *Pseudomonas* species, *Haemophilus influenzae*, *Haemophilus ducreyi*, other *Hemophilus* species, *Clostridium tetani*, other *Clostridium* species, *Yersinia enterocolitica*, and other *Yersinia* species.

**[0035]** Also disclosed are methods wherein the antigen is a fungal antigen. The antigen can be, for example, a peptide, polypeptide, or protein selected from the group of fungi consisting of *Candida albicans*, *Cryptococcus neoformans*, *Histoplasma capsulatum*, *Aspergillus fumigatus*, *Coccidioides immitis*, *Paracoccidioides brasiliensis*, *Blastomyces dermatitidis*, *Pneumocystis carinii*, *Penicillium marneffi*, and *Alternaria alternata*.

**[0036]** Also disclosed are methods wherein the antigen is a parasite antigen. The antigen can be, for example, a peptide, polypeptide, or protein selected from the group of parasitic organisms consisting of *Toxoplasma gondii*, *Plasmodium falciparum*, *Plasmodium vivax*, *Plasmodium malariae*, other *Plasmodium* species, *Trypanosoma brucei*, *Trypanosoma cruzi*, *Leishmania major*, other *Leishmania* species, *Schistosoma mansoni*, other *Schistosoma* species, and *Entamoeba histolytica*.

**[0037]** Also disclosed are methods wherein the antigen is a toxin. It is understood that such toxins can include but are not limited to Abrin, Conotoxins Diacetoxyscirpenol Bovine spongiform encephalopathy agent, Ricin, Saxitoxin, Tetrodotoxin, epsilon toxin, Botulinum neurotoxins, Shigatoxin, Staphylococcal enterotoxins, T-2 toxin, Diphtheria toxin, Tetanus toxoid, and pertussis toxin.

**[0038]** Also disclosed are methods wherein the antigen is a cancer-related antigen. The antigen can be, for example, a peptide, polypeptide, or protein selected from the group of cancers consisting of lymphomas (Hodgkins and non-Hodgkins), B cell lymphoma, T cell lymphoma, myeloid leukemia, leukemias, mycosis fungoides, carcinomas, carcinomas of solid tissues, squamous cell carcinomas, adenocarcinomas, sarcomas, gliomas, blastomas, neuroblastomas, plasmacytomas, histiocytomas, melanomas, adenomas, hypoxic tumors, myelomas, AIDS-related lymphomas or sarcomas, metastatic cancers, bladder cancer, brain cancer, nervous system cancer, squamous cell carcinoma of head and neck, neuroblastoma/glioblastoma, ovarian cancer, skin cancer, liver cancer, melanoma, squamous cell carcinomas of the mouth, throat, larynx, and lung, colon cancer, cervical cancer, cervical carcinoma, breast cancer, epithelial cancer, renal cancer, genitourinary cancer, pulmonary cancer, esophageal carcinoma, head and neck carcinoma, hematopoietic cancers, testicular cancer, colo-rectal cancers, prostatic cancer, or pancreatic cancer.

**[0039]** The present methods can also be used to the efficacy of immune responses to an antigen related to an autoimmune or inflammatory condition. Such conditions include but are not limited to asthma, rheumatoid arthritis, reactive arthritis, spondylarthritis, systemic vasculitis, insulin dependent diabetes mellitus, multiple sclerosis, experimental allergic encephalomyelitis, Sjögren's syndrome, graft versus host disease, inflammatory bowel disease including Crohn's disease, ulcerative colitis, ischemia reperfusion injury, myocardial infarction, Alzheimer's disease, transplant rejection (allogeneic and xenogeneic), thermal trauma, any immune complex-induced inflammation, glomerulonephritis, myasthenia gravis, cerebral lupus, Guillaine-Barre syndrome, vasculitis, systemic sclerosis, anaphylaxis, catheter reactions, atheroma, infertility, thyroiditis, ARDS, post-bypass syndrome, hemodialysis, juvenile rheumatoid, Behcets syndrome, hemolytic anemia, pemphigus, bulbous pemphigoid, stroke, atherosclerosis, and scleroderma. In particular, the antigen can comprise an amyloid antigen (e.g., amyloid  $\beta$  peptide) thus providing an assessment of an immune response to Alzheimer's disease. Thus, disclosed herein are methods of assessing the effectiveness of a therapy for an autoimmune disease comprising obtaining peripheral blood mononuclear cells (PBMC) from the subject and measuring the presence of antibody secreting cells (ASC) in the PBMC, wherein the absence of ASC indicates an effective therapy.

**[0040]** Application for the clinical use of the ASC Elisposts directly ex vivo from the human blood include: diagnosis of

acute microbial infections such as viral, fungal, bacterial infections (especially difficult to diagnosis invasive *Staphylococcal* infections especially MRSA vs. colonization, bacterial pneumonia: *pneumococcal*, etc. fungal infections in the lung, CNS, or other invasive sites (i.e. *histoplasmosis*, *coccidiomycoses*, *cryptococcus*, etc.)); diagnosis of invasive vs. colonization of common flora such as *Candida* and *staphylococcus*; diagnosis of microbial exposure leading to autoimmune diseases; early biomarkers of antibody responses especially to assess humoral vaccine responses; identifying transplant recipients who may be at risk of developing alloantibodies post-tranplantation; and/or clinical assessment of general state of inflammation due to B cells by the increase in background frequencies of total Ig ASC (marker of inflammation such as CRP etc.).

#### Immunoassays

**[0041]** As shown herein, ASC can be detected by ELISPOT, but the transient presence of the antigen-specific ASC could also be used by detection of antigen-specific antibody secreted by the cells by ELISA which may be easier for clinical diagnostic laboratories to perform. The steps of various useful immunodetection methods have been described in the scientific literature, such as, e.g., Maggio et al., Enzyme-Immunoassay, (1987) and Nakamura, et al., Enzyme Immunoassays: Heterogeneous and Homogeneous Systems, Handbook of Experimental Immunology, Vol. 1: Immunochemistry, 27.1-27.20 (1986), each of which is incorporated herein by reference in its entirety and specifically for its teaching regarding immunodetection methods. Immunoassays, in their most simple and direct sense, are binding assays involving binding between antibodies and antigen. Many types and formats of immunoassays are known and all are suitable for detecting the disclosed biomarkers. Examples of immunoassays are enzyme linked immunosorbent assays (ELISAs), enzyme linked immunospot assay (ELISPOT), radioimmunoassays (RIA), radioimmune precipitation assays (RIPA), immunobead capture assays, Western blotting, dot blotting, gel-shift assays, Flow cytometry, protein arrays, multiplexed bead arrays, magnetic capture, in vivo imaging, fluorescence resonance energy transfer (FRET), and fluorescence recovery/localization after photobleaching (FRAP/FLAP).

**[0042]** In general, immunoassays involve contacting a sample suspected of containing a molecule of interest (such as the disclosed biomarkers) with an antibody to the molecule of interest or contacting an antibody to a molecule of interest (such as antibodies to the disclosed biomarkers) with a molecule that can be bound by the antibody, as the case may be, under conditions effective to allow the formation of immunocomplexes. Contacting a sample with the antibody to the molecule of interest or with the molecule that can be bound by an antibody to the molecule of interest under conditions effective and for a period of time sufficient to allow the formation of immune complexes (primary immune complexes) is generally a matter of simply bringing into contact the molecule or antibody and the sample and incubating the mixture for a period of time long enough for the antibodies to form immune complexes with, i.e., to bind to, any molecules (e.g., antigens) present to which the antibodies can bind. In many forms of immunoassay, the sample-antibody composition, such as a tissue section, ELISA plate, dot blot or Western blot, can then be washed to remove any non-specifically bound antibody

species, allowing only those antibodies specifically bound within the primary immune complexes to be detected.

**[0043]** Immunoassays can include methods for detecting or quantifying the amount of a molecule of interest (such as the disclosed biomarkers or their antibodies) in a sample, which methods generally involve the detection or quantitation of any immune complexes formed during the binding process. In general, the detection of immunocomplex formation is well known in the art and can be achieved through the application of numerous approaches. These methods are generally based upon the detection of a label or marker, such as any radioactive, fluorescent, biological or enzymatic tags or any other known label. See, for example, U.S. Pat. Nos. 3,817,837; 3,850,752; 3,939,350; 3,996,345; 4,277,437; 4,275,149 and 4,366,241, each of which is incorporated herein by reference in its entirety and specifically for teachings regarding immunodetection methods and labels.

**[0044]** As used herein, a label can include a fluorescent dye, a member of a binding pair, such as biotin/streptavidin, a metal (e.g., gold), or an epitope tag that can specifically interact with a molecule that can be detected, such as by producing a colored substrate or fluorescence. Substances suitable for detectably labeling proteins include fluorescent dyes (also known herein as fluorochromes and fluorophores) and enzymes that react with colorimetric substrates (e.g., horseradish peroxidase). The use of fluorescent dyes is generally preferred in the practice of the invention as they can be detected at very low amounts. Furthermore, in the case where multiple antigens are reacted with a single array, each antigen can be labeled with a distinct fluorescent compound for simultaneous detection. Labeled spots on the array are detected using a fluorimeter, the presence of a signal indicating an antigen bound to a specific antibody.

**[0045]** Fluorophores are compounds or molecules that luminesce. Typically fluorophores absorb electromagnetic energy at one wavelength and emit electromagnetic energy at a second wavelength. Representative fluorophores include, but are not limited to, 1,5 IAEDANS; 1,8-ANS; 4-Methylumbelliferone; 5-carboxy-2,7-dichlorofluorescein; 5-Carboxyfluorescein (5-FAM); 5-Carboxynaphthofluorescein; 5-Carboxytetramethylrhodamine (5-TAMRA); 5-Hydroxy Tryptamine (5-HAT); 5-ROX (carboxy-X-rhodamine); 6-Carboxyrhodamine 6G; 6-CR 6G; 6-JOE; 7-Amino-4-methylcoumarin; 7-Aminoactinomycin D (7-AAD); 7-Hydroxy-4-I methylcoumarin; 9-Amino-6-chloro-2-methoxy-acridine (ACMA); ABQ; Acid Fuchsin; Acridine Orange; Acridine Red; Acridine Yellow; Acriflavin; Acriflavin Feulgen SITS; Aequorin (Photoprotein); AFPs—AutoFluorescent Protein—(Quantum Biotechnologies) see sgGFP, sgBFP; Alexa Fluor 350<sup>TM</sup>; Alexa Fluor 430<sup>TM</sup>; Alexa Fluor 488<sup>TM</sup>; Alexa Fluor 532<sup>TM</sup>; Alexa Fluor 546<sup>TM</sup>; Alexa Fluor 568<sup>TM</sup>; Alexa Fluor 594<sup>TM</sup>; Alexa Fluor 633<sup>TM</sup>; Alexa Fluor 647<sup>TM</sup>; Alexa Fluor 660<sup>TM</sup>; Alexa Fluor 680<sup>TM</sup>; Alizarin Complexon; Alizarin Red; Allophycocyanin (APC); AMC, AMCA-S; Aminomethylcoumarin (AMCA); AMCA-X; Aminoactinomycin D; Aminocoumarin; Anilin Blue; Anthrocyll stearate; APC-Cy7; APTRA-BTC; APTS; Astrazon Brilliant Red 4G; Astrazon Orange R; Astrazon Red 6B; Astrazon Yellow 7 GLL; Atabrine; ATTO-TAG<sup>TM</sup> CBQCA; ATTO-TAG<sup>TM</sup> FQ; Auramine; Aurophosphine G; Aurophosphine; BAO 9 (Bisaminophenylloxadiazole); BCECF (high pH); BCECF (low pH); Berberine Sulphate; Beta Lactamase; BFP blue shifted GFP (Y66H); Blue Fluorescent Protein; BFP/GFP FRET; Bimane; Bisbenzamide; Bisbenzimidate

**[0046]** A modifier unit such as a radionuclide can be incorporated into or attached directly to any of the compounds described herein by halogenation. Examples of radionuclides useful in this embodiment include, but are not limited to, tritium, iodine-125, iodine-131, iodine-123, iodine-124, astatine-210, carbon-11, carbon-14, nitrogen-13, fluorine-18. In another aspect, the radionuclide can be attached to a linking group or bound by a chelating group, which is then attached to the compound directly or by means of a linker. Examples of radionuclides useful in the apset include, but are not limited to, Tc-99m, Re-186, Ga-68, Re-188, Y-90, Sm-153, Bi-212,

Cu-67, Cu-64, and Cu-62. Radiolabeling techniques such as these are routinely used in the radiopharmaceutical industry.

**[0047]** The radiolabeled compounds are useful as imaging agents to diagnose neurological disease (e.g., a neurodegenerative disease) or a mental condition or to follow the progression or treatment of such a disease or condition in a mammal (e.g., a human). The radiolabeled compounds described herein can be conveniently used in conjunction with imaging techniques such as positron emission tomography (PET) or single photon emission computerized tomography (SPECT).

**[0048]** Labeling can be either direct or indirect. In direct labeling, the detecting antibody (the antibody for the molecule of interest) or detecting molecule (the molecule that can be bound by an antibody to the molecule of interest) include a label. Detection of the label indicates the presence of the detecting antibody or detecting molecule, which in turn indicates the presence of the molecule of interest or of an antibody to the molecule of interest, respectively. In indirect labeling, an additional molecule or moiety is brought into contact with, or generated at the site of, the immunocomplex. For example, a signal-generating molecule or moiety such as an enzyme can be attached to or associated with the detecting antibody or detecting molecule. The signal-generating molecule can then generate a detectable signal at the site of the immunocomplex. For example, an enzyme, when supplied with suitable substrate, can produce a visible or detectable product at the site of the immunocomplex. ELISAs use this type of indirect labeling.

**[0049]** As another example of indirect labeling, an additional molecule (which can be referred to as a binding agent) that can bind to either the molecule of interest or to the antibody (primary antibody) to the molecule of interest, such as a second antibody to the primary antibody, can be contacted with the immunocomplex. The additional molecule can have a label or signal-generating molecule or moiety. The additional molecule can be an antibody, which can thus be termed a secondary antibody. Binding of a secondary antibody to the primary antibody can form a so-called sandwich with the first (or primary) antibody and the molecule of interest. The immune complexes can be contacted with the labeled, secondary antibody under conditions effective and for a period of time sufficient to allow the formation of secondary immune complexes. The secondary immune complexes can then be generally washed to remove any non-specifically bound labeled secondary antibodies, and the remaining label in the secondary immune complexes can then be detected. The additional molecule can also be or include one of a pair of molecules or moieties that can bind to each other, such as the biotin/avidin pair. In this mode, the detecting antibody or detecting molecule should include the other member of the pair.

**[0050]** Other modes of indirect labeling include the detection of primary immune complexes by a two step approach. For example, a molecule (which can be referred to as a first binding agent), such as an antibody, that has binding affinity for the molecule of interest or corresponding antibody can be used to form secondary immune complexes, as described above. After washing, the secondary immune complexes can be contacted with another molecule (which can be referred to as a second binding agent) that has binding affinity for the first binding agent, again under conditions effective and for a period of time sufficient to allow the formation of immune complexes (thus forming tertiary immune complexes). The

second binding agent can be linked to a detectable label or signal-generating molecule or moiety, allowing detection of the tertiary immune complexes thus formed. This system can provide for signal amplification.

**[0051]** Immunoassays that involve the detection of a substance, such as a protein or an antibody to a specific protein, include label-free assays, protein separation methods (i.e., electrophoresis), solid support capture assays, or *in vivo* detection. Label-free assays are generally diagnostic means of determining the presence or absence of a specific protein, or an antibody to a specific protein, in a sample. Protein separation methods are additionally useful for evaluating physical properties of the protein, such as size or net charge. Capture assays are generally more useful for quantitatively evaluating the concentration of a specific protein, or antibody to a specific protein, in a sample. Finally, *in vivo* detection is useful for evaluating the spatial expression patterns of the substance, i.e., where the substance can be found in a subject, tissue or cell.

**[0052]** Provided that the concentrations are sufficient, the molecular complexes ([Ab-Ag]<sub>n</sub>) generated by antibody—antigen interaction are visible to the naked eye, but smaller amounts may also be detected and measured due to their ability to scatter a beam of light. The formation of complexes indicates that both reactants are present, and in immunoprecipitation assays a constant concentration of a reagent antibody is used to measure specific antigen ([Ab-Ag]<sub>n</sub>), and reagent antigens are used to detect specific antibody ([Ab-Ag]<sub>n</sub>). If the reagent species is previously coated onto cells (as in hemagglutination assay) or very small particles (as in latex agglutination assay), “clumping” of the coated particles is visible at much lower concentrations. A variety of assays based on these elementary principles are in common use, including Ouchterlony immunodiffusion assay, rocket immunoelectrophoresis, and immunoturbidometric and nephelometric assays. The main limitations of such assays are restricted sensitivity (lower detection limits) in comparison to assays employing labels and, in some cases, the fact that very high concentrations of analyte can actually inhibit complex formation, necessitating safeguards that make the procedures more complex. Some of these Group 1 assays date right back to the discovery of antibodies and none of them have an actual “label” (e.g. Ag-enz). Other kinds of immunoassays that are label free depend on immunosensors, and a variety of instruments that can directly detect antibody—antigen interactions are now commercially available. Most depend on generating an evanescent wave on a sensor surface with immobilized ligand, which allows continuous monitoring of binding to the ligand. Immunosensors allow the easy investigation of kinetic interactions and, with the advent of lower-cost specialized instruments, may in the future find wide application in immunoanalysis.

**[0053]** The use of immunoassays to detect a specific protein can involve the separation of the proteins by electrophoresis. Electrophoresis is the migration of charged molecules in solution in response to an electric field. Their rate of migration depends on the strength of the field; on the net charge, size and shape of the molecules and also on the ionic strength, viscosity and temperature of the medium in which the molecules are moving. As an analytical tool, electrophoresis is simple, rapid and highly sensitive. It is used analytically to study the properties of a single charged species, and as a separation technique.

**[0054]** Generally the sample is run in a support matrix such as paper, cellulose acetate, starch gel, agarose or polyacrylamide gel. The matrix inhibits convective mixing caused by heating and provides a record of the electrophoretic run: at the end of the run, the matrix can be stained and used for scanning, autoradiography or storage. In addition, the most commonly used support matrices—agarose and polyacrylamide—provide a means of separating molecules by size, in that they are porous gels. A porous gel may act as a sieve by retarding, or in some cases completely obstructing, the movement of large macromolecules while allowing smaller molecules to migrate freely. Because dilute agarose gels are generally more rigid and easy to handle than polyacrylamide of the same concentration, agarose is used to separate larger macromolecules such as nucleic acids, large proteins and protein complexes. Polyacrylamide, which is easy to handle and to make at higher concentrations, is used to separate most proteins and small oligonucleotides that require a small gel pore size for retardation.

**[0055]** Proteins are amphoteric compounds; their net charge therefore is determined by the pH of the medium in which they are suspended. In a solution with a pH above its isoelectric point, a protein has a net negative charge and migrates towards the anode in an electrical field. Below its isoelectric point, the protein is positively charged and migrates towards the cathode. The net charge carried by a protein is in addition independent of its size—i.e., the charge carried per unit mass (or length), given proteins and nucleic acids are linear macromolecules) of molecule differs from protein to protein. At a given pH therefore, and under non-denaturing conditions, the electrophoretic separation of proteins is determined by both size and charge of the molecules.

**[0056]** Sodium dodecyl sulphate (SDS) is an anionic detergent which denatures proteins by “wrapping around” the polypeptide backbone—and SDS binds to proteins fairly specifically in a mass ratio of 1.4:1. In so doing, SDS confers a negative charge to the polypeptide in proportion to its length. Further, it is usually necessary to reduce disulphide bridges in proteins (denature) before they adopt the random-coil configuration necessary for separation by size; this is done with 2-mercaptoethanol or dithiothreitol (DTT). In denaturing SDS-PAGE separations therefore, migration is determined not by intrinsic electrical charge of the polypeptide, but by molecular weight.

**[0057]** Determination of molecular weight is done by SDS-PAGE of proteins of known molecular weight along with the protein to be characterized. A linear relationship exists between the logarithm of the molecular weight of an SDS-denatured polypeptide, or native nucleic acid, and its R<sub>f</sub>. The R<sub>f</sub> is calculated as the ratio of the distance migrated by the molecule to that migrated by a marker dye-front. A simple way of determining relative molecular weight by electrophoresis (Mr) is to plot a standard curve of distance migrated vs. log 10MW for known samples, and read off the log Mr of the sample after measuring distance migrated on the same gel.

**[0058]** In two-dimensional electrophoresis, proteins are fractionated first on the basis of one physical property, and, in a second step, on the basis of another. For example, isoelectric focusing can be used for the first dimension, conveniently carried out in a tube gel, and SDS electrophoresis in a slab gel can be used for the second dimension. One example of a procedure is that of O'Farrell, P. H., High Resolution Two-dimensional Electrophoresis of Proteins, *J. Biol. Chem.* 250: 4007-4021 (1975), herein incorporated by reference in its

entirety for its teaching regarding two-dimensional electrophoresis methods. Other examples include but are not limited to, those found in Anderson, L and Anderson, N G, High resolution two-dimensional electrophoresis of human plasma proteins, Proc. Natl. Acad. Sci. 74:5421-5425 (1977), Ornstein, L., Disc electrophoresis, L. Ann. N.Y. Acad. Sci. 121: 321349 (1964), each of which is herein incorporated by reference in its entirety for teachings regarding electrophoresis methods.

**[0059]** Laemmli, U. K., Cleavage of structural proteins during the assembly of the head of bacteriophage T4, Nature 227:680 (1970), which is herein incorporated by reference in its entirety for teachings regarding electrophoresis methods, discloses a discontinuous system for resolving proteins denatured with SDS. The leading ion in the Laemmli buffer system is chloride, and the trailing ion is glycine. Accordingly, the resolving gel and the stacking gel are made up in Tris-HCl buffers (of different concentration and pH), while the tank buffer is Tris-glycine. All buffers contain 0.1% SDS.

**[0060]** One example of an immunoassay that uses electrophoresis that is contemplated in the current methods is Western blot analysis. Western blotting or immunoblotting allows the determination of the molecular mass of a protein and the measurement of relative amounts of the protein present in different samples. Detection methods include chemiluminescence and chromagenic detection. Standard methods for Western blot analysis can be found in, for example, D. M. Bollag et al., *Protein Methods* (2d edition 1996) and E. Harlow & D. Lane, *Antibodies, a Laboratory Manual* (1988), U.S. Pat. No. 4,452,901, each of which is herein incorporated by reference in their entirety for teachings regarding Western blot methods. Generally, proteins are separated by gel electrophoresis, usually SDS-PAGE. The proteins are transferred to a sheet of special blotting paper, e.g., nitrocellulose, though other types of paper, or membranes, can be used. The proteins retain the same pattern of separation they had on the gel. The blot is incubated with a generic protein (such as milk proteins) to bind to any remaining sticky places on the nitrocellulose. An antibody is then added to the solution which is able to bind to its specific protein.

**[0061]** The attachment of specific antibodies to specific immobilized antigens can be readily visualized by indirect enzyme immunoassay techniques, usually using a chromogenic substrate (e.g. alkaline phosphatase or horseradish peroxidase) or chemiluminescent substrates. Other possibilities for probing include the use of fluorescent or radioisotope labels (e.g., fluorescein, <sup>125</sup>I). Probes for the detection of antibody binding can be conjugated anti-immunoglobulins, conjugated staphylococcal Protein A (binds IgG), or probes to biotinylated primary antibodies (e.g., conjugated avidin/streptavidin).

**[0062]** The power of the technique lies in the simultaneous detection of a specific protein by means of its antigenicity, and its molecular mass. Proteins are first separated by mass in the SDS-PAGE, then specifically detected in the immunoassay step. Thus, protein standards (ladders) can be run simultaneously in order to approximate molecular mass of the protein of interest in a heterogeneous sample.

**[0063]** The gel shift assay or electrophoretic mobility shift assay (EMSA) can be used to detect the interactions between DNA binding proteins and their cognate DNA recognition sequences, in both a qualitative and quantitative manner. Exemplary techniques are described in Ornstein L., Disc electrophoresis—I: Background and theory, Ann. NY Acad.

Sci. 121:321-349 (1964), and Matsudaira, P T and D R Burgess, SDS microslab linear gradient polyacrylamide gel electrophoresis, Anal. Biochem. 87:386-396 (1987), each of which is herein incorporated by reference in its entirety for teachings regarding gel-shift assays.

**[0064]** In a general gel-shift assay, purified proteins or crude cell extracts can be incubated with a labeled (e.g., <sup>32</sup>P-radiolabeled) DNA or RNA probe, followed by separation of the complexes from the free probe through a non-denaturing polyacrylamide gel. The complexes migrate more slowly through the gel than unbound probe. Depending on the activity of the binding protein, a labeled probe can be either double-stranded or single-stranded. For the detection of DNA binding proteins such as transcription factors, either purified or partially purified proteins, or nuclear cell extracts can be used. For detection of RNA binding proteins, either purified or partially purified proteins, or nuclear or cytoplasmic cell extracts can be used. The specificity of the DNA or RNA binding protein for the putative binding site is established by competition experiments using DNA or RNA fragments or oligonucleotides containing a binding site for the protein of interest, or other unrelated sequence. The differences in the nature and intensity of the complex formed in the presence of specific and nonspecific competitor allows identification of specific interactions. Refer to Promega, Gel Shift Assay FAQ, available at <<http://www.promega.com/faq/gelshfaq.html>> (last visited Mar. 25, 2005), which is herein incorporated by reference in its entirety for teachings regarding gel shift methods.

**[0065]** Gel shift methods can include using, for example, colloidal forms of COOMASSIE (Imperial Chemicals Industries, Ltd) blue stain to detect proteins in gels such as polyacrylamide electrophoresis gels. Such methods are described, for example, in Neuhoff et al., Electrophoresis 6:427-448 (1985), and Neuhoff et al., Electrophoresis 9:255-262 (1988), each of which is herein incorporated by reference in its entirety for teachings regarding gel shift methods. In addition to the conventional protein assay methods referenced above, a combination cleaning and protein staining composition is described in U.S. Pat. No. 5,424,000, herein incorporated by reference in its entirety for its teaching regarding gel shift methods. The solutions can include phosphoric, sulfuric, and nitric acids, and Acid Violet dye.

**[0066]** Radioimmune Precipitation Assay (RIPA) is a sensitive assay using radiolabeled antigens to detect specific antibodies in serum. The antigens are allowed to react with the serum and then precipitated using a special reagent such as, for example, protein A sepharose beads. The bound radiolabeled immunoprecipitate is then commonly analyzed by gel electrophoresis. Radioimmunoprecipitation assay (RIPA) is often used as a confirmatory test for diagnosing the presence of HIV antibodies. RIPA is also referred to in the art as Farr Assay, Precipitin Assay, Radioimmune Precipitin Assay; Radioimmunoprecipitation Analysis; Radioimmunoprecipitation Analysis, and Radioimmunoprecipitation Analysis.

**[0067]** While the above immunoassays that utilize electrophoresis to separate and detect the specific proteins of interest allow for evaluation of protein size, they are not very sensitive for evaluating protein concentration. However, also contemplated are immunoassays wherein the protein or antibody specific for the protein is bound to a solid support (e.g., tube, well, bead, or cell) to capture the antibody or protein of interest, respectively, from a sample, combined with a method of detecting the protein or antibody specific for the

protein on the support. Examples of such immunoassays include Radioimmunoassay (RIA), Enzyme-Linked Immunosorbent Assay (ELISA), Flow cytometry, protein array, multiplexed bead assay, and magnetic capture.

**[0068]** Radioimmunoassay (RIA) is a classic quantitative assay for detection of antigen-antibody reactions using a radioactively labeled substance (radioligand), either directly or indirectly, to measure the binding of the unlabeled substance to a specific antibody or other receptor system. Radioimmunoassay is used, for example, to test hormone levels in the blood without the need to use a bioassay. Non-immunogenic substances (e.g., haptens) can also be measured if coupled to larger carrier proteins (e.g., bovine gamma-globulin or human serum albumin) capable of inducing antibody formation. RIA involves mixing a radioactive antigen (because of the ease with which iodine atoms can be introduced into tyrosine residues in a protein, the radioactive isotopes  $^{125}\text{I}$  or  $^{131}\text{I}$  are often used) with antibody to that antigen. The antibody is generally linked to a solid support, such as a tube or beads. Unlabeled or “cold” antigen is then added in known quantities and measuring the amount of labeled antigen displaced. Initially, the radioactive antigen is bound to the antibodies. When cold antigen is added, the two compete for antibody binding sites—and at higher concentrations of cold antigen, more binds to the antibody, displacing the radioactive variant. The bound antigens are separated from the unbound ones in solution and the radioactivity of each used to plot a binding curve. The technique is both extremely sensitive, and specific.

**[0069]** Enzyme-Linked Immunospot Assay (ELISPOT) is an immunoassay that can detect an antibody specific for a protein or antigen. In such an assay, a detectable label bound to either an antibody-binding or antigen-binding reagent is an enzyme. When exposed to its substrate, this enzyme reacts in such a manner as to produce a chemical moiety which can be detected, for example, by spectrophotometric, fluorometric or visual means. Enzymes which can be used to detectably label reagents useful for detection include, but are not limited to, horseradish peroxidase, alkaline phosphatase, glucose oxidase,  $\beta$ -galactosidase, ribonuclease, urease, catalase, malate dehydrogenase, staphylococcal nuclease, asparaginase, yeast alcohol dehydrogenase, alpha.-glycerophosphate dehydrogenase, triose phosphate isomerase, glucose-6-phosphate dehydrogenase, glucoamylase and acetylcholinesterase. In this assay a nitrocellulose microtiter plate is coated with antigen. The test sample is exposed to the antigen and then reacted similarly to an ELISA assay. Detection differs from a traditional ELISA in that detection is determined by the enumeration of spots on the nitrocellulose plate. The presence of a spot indicates that the sample reacted to the antigen. The spots can be counted and the number of cells in the sample specific for the antigen determined.

**[0070]** Enzyme-Linked Immunosorbent Assay (ELISA), or more generically termed EIA (Enzyme ImmunoAssay), is an immunoassay that can detect an antibody specific for a protein. In such an assay, a detectable label bound to either an antibody-binding or antigen-binding reagent is an enzyme. When exposed to its substrate, this enzyme reacts in such a manner as to produce a chemical moiety which can be detected, for example, by spectrophotometric, fluorometric or visual means. Enzymes which can be used to detectably label reagents useful for detection include, but are not limited to, horseradish peroxidase, alkaline phosphatase, glucose oxidase,  $\beta$ -galactosidase, ribonuclease, urease, catalase,

malate dehydrogenase, staphylococcal nuclease, asparaginase, yeast alcohol dehydrogenase, alpha.-glycerophosphate dehydrogenase, triose phosphate isomerase, glucose-6-phosphate dehydrogenase, glucoamylase and acetylcholinesterase. For descriptions of ELISA procedures, see Voller, A. et al., *J. Clin. Pathol.* 31:507-520 (1978); Butler, J. E., *Meth. Enzymol.* 73:482-523 (1981); Maggio, E. (ed.), *Enzyme Immunoassay*, CRC Press, Boca Raton, 1980; Butler, J. E., In: *Structure of Antigens*, Vol. 1 (Van Regenmortel, M., CRC Press, Boca Raton, 1992, pp. 209-259; Butler, J. E., In: van Oss, C. J. et al., (eds), *Immunochemistry*, Marcel Dekker, Inc., New York, 1994, pp. 759-803; Butler, J. E. (ed.), *Immunochemistry of Solid-Phase Immunoassay*, CRC Press, Boca Raton, 1991); Crowther, “ELISA: Theory and Practice,” In: *Methods in Molecule Biology*, Vol. 42, Humana Press; New Jersey, 1995; U.S. Pat. No. 4,376,110, each of which is incorporated herein by reference in its entirety and specifically for teachings regarding ELISA methods.

**[0071]** Variations of ELISA techniques are known to those of skill in the art. In one variation, antibodies that can bind to proteins can be immobilized onto a selected surface exhibiting protein affinity, such as a well in a polystyrene microtiter plate. Then, a test composition suspected of containing a marker antigen can be added to the wells. After binding and washing to remove non-specifically bound immunocomplexes, the bound antigen can be detected. Detection can be achieved by the addition of a second antibody specific for the target protein, which is linked to a detectable label. This type of ELISA is a simple “sandwich ELISA.” Detection also can be achieved by the addition of a second antibody, followed by the addition of a third antibody that has binding affinity for the second antibody, with the third antibody being linked to a detectable label.

**[0072]** Another variation is a competition ELISA. In competition ELISA's, test samples compete for binding with known amounts of labeled antigens or antibodies. The amount of reactive species in the sample can be determined by mixing the sample with the known labeled species before or during incubation with coated wells. The presence of reactive species in the sample acts to reduce the amount of labeled species available for binding to the well and thus reduces the ultimate signal.

**[0073]** Regardless of the format employed, ELISAs have certain features in common, such as coating, incubating or binding, washing to remove non-specifically bound species, and detecting the bound immunocomplexes. Antigen or antibodies can be linked to a solid support, such as in the form of plate, beads, dipstick, membrane or column matrix, and the sample to be analyzed applied to the immobilized antigen or antibody. In coating a plate with either antigen or antibody, one will generally incubate the wells of the plate with a solution of the antigen or antibody, either overnight or for a specified period of hours. The wells of the plate can then be washed to remove incompletely adsorbed material. Any remaining available surfaces of the wells can then be “coated” with a nonspecific protein that is antigenically neutral with regard to the test antisera. These include bovine serum albumin (BSA), casein and solutions of milk powder. The coating allows for blocking of nonspecific adsorption sites on the immobilizing surface and thus reduces the background caused by nonspecific binding of antisera onto the surface.

**[0074]** In ELISAs, a secondary or tertiary detection means rather than a direct procedure can also be used. Thus, after binding of a protein or antibody to the well, coating with a

non-reactive material to reduce background, and washing to remove unbound material, the immobilizing surface is contacted with the control clinical or biological sample to be tested under conditions effective to allow immunocomplex (antigen/antibody) formation. Detection of the immunocomplex then requires a labeled secondary binding agent or a secondary binding agent in conjunction with a labeled third binding agent.

**[0075]** “Under conditions effective to allow immunocomplex (antigen/antibody) formation” means that the conditions include diluting the antigens and antibodies with solutions such as BSA, bovine gamma globulin (BGG) and phosphate buffered saline (PBS)/Tween so as to reduce non-specific binding and to promote a reasonable signal to noise ratio.

**[0076]** The suitable conditions also mean that the incubation is at a temperature and for a period of time sufficient to allow effective binding. Incubation steps can typically be from about 1 minute to twelve hours, at temperatures of about 20° to 30° C., or can be incubated overnight at about 0° C. to about 10° C.

**[0077]** Following all incubation steps in an ELISA, the contacted surface can be washed so as to remove non-complexed material. A washing procedure can include washing with a solution such as PBS/Tween or borate buffer. Following the formation of specific immunocomplexes between the test sample and the originally bound material, and subsequent washing, the occurrence of even minute amounts of immunocomplexes can be determined.

**[0078]** To provide a detecting means, the second or third antibody can have an associated label to allow detection, as described above. This can be an enzyme that can generate color development upon incubating with an appropriate chromogenic substrate. Thus, for example, one can contact and incubate the first or second immunocomplex with a labeled antibody for a period of time and under conditions that favor the development of further immunocomplex formation (e.g., incubation for 2 hours at room temperature in a PBS-containing solution such as PBS-Tween).

**[0079]** After incubation with the labeled antibody, and subsequent to washing to remove unbound material, the amount of label can be quantified, e.g., by incubation with a chromogenic substrate such as urea and bromocresol purple or 2,2'-azido-di-(3-ethyl-benzthiazoline-6-sulfonic acid [ABTS] and H<sub>2</sub>O<sub>2</sub>, in the case of peroxidase as the enzyme label. Quantitation can then be achieved by measuring the degree of color generation, e.g., using a visible spectra spectrophotometer.

**[0080]** Protein arrays are solid-phase ligand binding assay systems using immobilized proteins on surfaces which include glass, membranes, microtiter wells, mass spectrometer plates, and beads or other particles. The assays are highly parallel (multiplexed) and often miniaturized (microarrays, protein chips). Their advantages include being rapid and automatable, capable of high sensitivity, economical on reagents, and giving an abundance of data for a single experiment. Bioinformatics support is important; the data handling demands sophisticated software and data comparison analysis. However, the software can be adapted from that used for DNA arrays, as can much of the hardware and detection systems.

**[0081]** One of the chief formats is the capture array, in which ligand-binding reagents, which are usually antibodies but can also be alternative protein scaffolds, peptides or nucleic acid aptamers, are used to detect target molecules in

mixtures such as plasma or tissue extracts. In diagnostics, capture arrays can be used to carry out multiple immunoassays in parallel, both testing for several analytes in individual sera for example and testing many serum samples simultaneously. In proteomics, capture arrays are used to quantitate and compare the levels of proteins in different samples in health and disease, i.e. protein expression profiling. Proteins other than specific ligand binders are used in the array format for in vitro functional interaction screens such as protein-protein, protein-DNA, protein-drug, receptor-ligand, enzyme-substrate, etc. The capture reagents themselves are selected and screened against many proteins, which can also be done in a multiplex array format against multiple protein targets.

**[0082]** For construction of arrays, sources of proteins include cell-based expression systems for recombinant proteins, purification from natural sources, production in vitro by cell-free translation systems, and synthetic methods for peptides. Many of these methods can be automated for high throughput production. For capture arrays and protein function analysis, it is important that proteins should be correctly folded and functional; this is not always the case, e.g. where recombinant proteins are extracted from bacteria under denaturing conditions. Nevertheless, arrays of denatured proteins are useful in screening antibodies for cross-reactivity, identifying autoantibodies and selecting ligand binding proteins.

**[0083]** Protein arrays have been designed as a miniaturization of familiar immunoassay methods such as ELISA and dot blotting, often utilizing fluorescent readout, and facilitated by robotics and high throughput detection systems to enable multiple assays to be carried out in parallel. Commonly used physical supports include glass slides, silicon, microwells, nitrocellulose or PVDF membranes, and magnetic and other microbeads. While microdrops of protein delivered onto planar surfaces are the most familiar format, alternative architectures include CD centrifugation devices based on developments in microfluidics (Gyros, Monmouth Junction, N.J.) and specialised chip designs, such as engineered microchannels in a plate (e.g., The Living Chip™, Biotrove, Woburn, Mass.) and tiny 3D posts on a silicon surface (Zyomyx, Hayward Calif.). Particles in suspension can also be used as the basis of arrays, providing they are coded for identification; systems include colour coding for microbeads (Luminex, Austin, Tex.; Bio-Rad Laboratories) and semiconductor nanocrystals (e.g., QDots™, Quantum Dot, Hayward, Calif.), and barcoding for beads (UltraPlex™, SmartBead Technologies Ltd, Babraham, Cambridge, UK) and multimetal microrods (e.g., Nanobarcodes™ particles, Nanoplex Technologies, Mountain View, Calif.). Beads can also be assembled into planar arrays on semiconductor chips (LEAPS technology, BioArray Solutions, Warren, N.J.).

**[0084]** Immobilization of proteins involves both the coupling reagent and the nature of the surface being coupled to. A good protein array support surface is chemically stable before and after the coupling procedures, allows good spot morphology, displays minimal nonspecific binding, does not contribute a background in detection systems, and is compatible with different detection systems. The immobilization method used are reproducible, applicable to proteins of different properties (size, hydrophilic, hydrophobic), amenable to high throughput and automation, and compatible with retention of fully functional protein activity. Orientation of the surface-bound protein is recognized as an important factor in presenting it to ligand or substrate in an active state; for

capture arrays the most efficient binding results are obtained with orientated capture reagents, which generally require site-specific labeling of the protein.

**[0085]** Both covalent and noncovalent methods of protein immobilization are used and have various pros and cons. Passive adsorption to surfaces is methodologically simple, but allows little quantitative or orientational control; it may or may not alter the functional properties of the protein, and reproducibility and efficiency are variable. Covalent coupling methods provide a stable linkage, can be applied to a range of proteins and have good reproducibility; however, orientation may be variable, chemical derivatization may alter the function of the protein and requires a stable interactive surface. Biological capture methods utilizing a tag on the protein provide a stable linkage and bind the protein specifically and in reproducible orientation, but the biological reagent must first be immobilized adequately and the array may require special handling and have variable stability.

**[0086]** Several immobilization chemistries and tags have been described for fabrication of protein arrays. Substrates for covalent attachment include glass slides coated with amino- or aldehyde-containing silane reagents. In the Versalinx™ system (ProLinx, Bothell, Wash.) reversible covalent coupling is achieved by interaction between the protein derivatised with phenyldiboronic acid, and salicylhydroxamic acid immobilized on the support surface. This also has low background binding and low intrinsic fluorescence and allows the immobilized proteins to retain function. Noncovalent binding of unmodified protein occurs within porous structures such as HydroGel™ (PerkinElmer, Wellesley, Mass.), based on a 3-dimensional polyacrylamide gel; this substrate is reported to give a particularly low background on glass microarrays, with a high capacity and retention of protein function. Widely used biological coupling methods are through biotin/streptavidin or hexahistidine/Ni interactions, having modified the protein appropriately. Biotin may be conjugated to a poly-lysine backbone immobilised on a surface such as titanium dioxide (Zyomyx) or tantalum pentoxide (Zeptosens, Witterswil, Switzerland).

**[0087]** Array fabrication methods include robotic contact printing, ink-jetting, piezoelectric spotting and photolithography. A number of commercial arrayers are available [e.g. Packard Biosciences] as well as manual equipment [V & P Scientific]. Bacterial colonies can be robotically gridded onto PVDF membranes for induction of protein expression in situ.

**[0088]** At the limit of spot size and density are nanoarrays, with spots on the nanometer spatial scale, enabling thousands of reactions to be performed on a single chip less than 1 mm square. BioForce Laboratories have developed nanoarrays with 1521 protein spots in 85 sq microns, equivalent to 25 million spots per sq cm, at the limit for optical detection; their readout methods are fluorescence and atomic force microscopy (AFM).

**[0089]** Fluorescence labeling and detection methods are widely used. The same instrumentation as used for reading DNA microarrays is applicable to protein arrays. For differential display, capture (e.g., antibody) arrays can be probed with fluorescently labeled proteins from two different cell states, in which cell lysates are directly conjugated with different fluorophores (e.g. Cy-3, Cy-5) and mixed, such that the color acts as a readout for changes in target abundance. Fluorescent readout sensitivity can be amplified 10-100 fold by tyramide signal amplification (TSA) (PerkinElmer Life-sciences). Planar waveguide technology (Zeptosens) enables

ultrasensitive fluorescence detection, with the additional advantage of no intervening washing procedures. High sensitivity can also be achieved with suspension beads and particles, using phycoerythrin as label (Luminex) or the properties of semiconductor nanocrystals (Quantum Dot). A number of novel alternative readouts have been developed, especially in the commercial biotech arena. These include adaptations of surface plasmon resonance (HTS Biosystems, Intrinsic Bioprobes, Tempe, Ariz.), rolling circle DNA amplification (Molecular Staging, New Haven Conn.), mass spectrometry (Intrinsic Bioprobes; CIPHERgen, Fremont, Calif.), resonance light scattering (Genicon Sciences, San Diego, Calif.) and atomic force microscopy [BioForce Laboratories].

**[0090]** Capture arrays form the basis of diagnostic chips and arrays for expression profiling. They employ high affinity capture reagents, such as conventional antibodies, single domains, engineered scaffolds, peptides or nucleic acid aptamers, to bind and detect specific target ligands in high throughput manner.

**[0091]** Antibody arrays have the required properties of specificity and acceptable background, and some are available commercially (BD Biosciences, San Jose, Calif.; Clontech, Mountain View, Calif.; BioRad; Sigma, St. Louis, Mo.). Antibodies for capture arrays are made either by conventional immunization (polyclonal sera and hybridomas), or as recombinant fragments, usually expressed in *E. coli*, after selection from phage or ribosome display libraries (Cambridge Antibody Technology, Cambridge, UK; BioInvent, Lund, Sweden; Affitech, Walnut Creek, Calif.; Biosite, San Diego, Calif.). In addition to the conventional antibodies, Fab and scFv fragments, single V-domains from camelids or engineered human equivalents (Domantis, Waltham, Mass.) may also be useful in arrays.

**[0092]** The term “scaffold” refers to ligand-binding domains of proteins, which are engineered into multiple variants capable of binding diverse target molecules with antibody-like properties of specificity and affinity. The variants can be produced in a genetic library format and selected against individual targets by phage, bacterial or ribosome display. Such ligand-binding scaffolds or frameworks include ‘Affibodies’ based on *Staph. aureus* protein A (Affibody, Bromma, Sweden), ‘Trinectins’ based on fibronectins (Phyllos, Lexington, Mass.) and ‘Anticalins’ based on the lipocalin structure (Pieris Proteolab, Freising-Weihenstephan, Germany). These can be used on capture arrays in a similar fashion to antibodies and may have advantages of robustness and ease of production.

**[0093]** Nonprotein capture molecules, notably the single-stranded nucleic acid aptamers which bind protein ligands with high specificity and affinity, are also used in arrays (SomaLogic, Boulder, Colo.). Aptamers are selected from libraries of oligonucleotides by the Selex™ procedure and their interaction with protein can be enhanced by covalent attachment, through incorporation of brominated deoxyuridine and UV-activated crosslinking (photoaptamers). Photocrosslinking to ligand reduces the crossreactivity of aptamers due to the specific steric requirements. Aptamers have the advantages of ease of production by automated oligonucleotide synthesis and the stability and robustness of DNA; on photoaptamer arrays, universal fluorescent protein stains can be used to detect binding.

**[0094]** Protein analytes binding to antibody arrays may be detected directly or via a secondary antibody in a sandwich

assay. Direct labelling is used for comparison of different samples with different colours. Where pairs of antibodies directed at the same protein ligand are available, sandwich immunoassays provide high specificity and sensitivity and are therefore the method of choice for low abundance proteins such as cytokines; they also give the possibility of detection of protein modifications. Label-free detection methods, including mass spectrometry, surface plasmon resonance and atomic force microscopy, avoid alteration of ligand. What is required from any method is optimal sensitivity and specificity, with low background to give high signal to noise. Since analyte concentrations cover a wide range, sensitivity has to be tailored appropriately; serial dilution of the sample or use of antibodies of different affinities are solutions to this problem. Proteins of interest are frequently those in low concentration in body fluids and extracts, requiring detection in the pg range or lower, such as cytokines or the low expression products in cells.

**[0095]** An alternative to an array of capture molecules is one made through 'molecular imprinting' technology, in which peptides (e.g., from the C-terminal regions of proteins) are used as templates to generate structurally complementary, sequence-specific cavities in a polymerizable matrix; the cavities can then specifically capture (denatured) proteins that have the appropriate primary amino acid sequence (ProteinPrint™, Aspira Biosystems, Burlingame, Calif.).

**[0096]** Another methodology which can be used diagnostically and in expression profiling is the ProteinChip® array (CIPHERGEN, Fremont, Calif.), in which solid phase chromatographic surfaces bind proteins with similar characteristics of charge or hydrophobicity from mixtures such as plasma or tumour extracts, and SELDI-TOF mass spectrometry is used to detection the retained proteins.

**[0097]** Large-scale functional chips have been constructed by immobilizing large numbers of purified proteins and used to assay a wide range of biochemical functions, such as protein interactions with other proteins, drug-target interactions, enzyme-substrates, etc. Generally they require an expression library, cloned into *E. coli*, yeast or similar from which the expressed proteins are then purified, e.g. via a His tag, and immobilized. Cell free protein transcription/translation is a viable alternative for synthesis of proteins which do not express well in bacterial or other *in vivo* systems.

**[0098]** For detecting protein-protein interactions, protein arrays can be *in vitro* alternatives to the cell-based yeast two-hybrid system and may be useful where the latter is deficient, such as interactions involving secreted proteins or proteins with disulphide bridges. High-throughput analysis of biochemical activities on arrays has been described for yeast protein kinases and for various functions (protein-protein and protein-lipid interactions) of the yeast proteome, where a large proportion of all yeast open-reading frames was expressed and immobilised on a microarray. Large-scale 'proteome chips' promise to be very useful in identification of functional interactions, drug screening, etc. (Proteometrix, Branford, Conn.).

**[0099]** As a two-dimensional display of individual elements, a protein array can be used to screen phage or ribosome display libraries, in order to select specific binding partners, including antibodies, synthetic scaffolds, peptides and aptamers. In this way, 'library against library' screening can be carried out. Screening of drug candidates in combina-

torial chemical libraries against an array of protein targets identified from genome projects is another application of the approach.

**[0100]** A multiplexed bead assay, such as, for example, the BD™ Cytometric Bead Array, is a series of spectrally discrete particles that can be used to capture and quantitate soluble analytes. The analyte is then measured by detection of a fluorescence-based emission and flow cytometric analysis. Multiplexed bead assay generates data that is comparable to ELISA based assays, but in a "multiplexed" or simultaneous fashion. Concentration of unknowns is calculated for the cytometric bead array as with any sandwich format assay, i.e. through the use of known standards and plotting unknowns against a standard curve. Further, multiplexed bead assay allows quantification of soluble analytes in samples never previously considered due to sample volume limitations. In addition to the quantitative data, powerful visual images can be generated revealing unique profiles or signatures that provide the user with additional information at a glance.

**[0101]** 1. Antibodies

**[0102]** As used herein, the term "antibody" encompasses, but is not limited to, whole immunoglobulin (i.e., an intact antibody) of any class. Native antibodies are usually heterotetrameric glycoproteins, composed of two identical light (L) chains and two identical heavy (H) chains. Typically, each light chain is linked to a heavy chain by one covalent disulfide bond, while the number of disulfide linkages varies between the heavy chains of different immunoglobulin isotypes. Each heavy and light chain also has regularly spaced intrachain disulfide bridges. Each heavy chain has at one end a variable domain (V(H)) followed by a number of constant domains. Each light chain has a variable domain at one end (V(L)) and a constant domain at its other end; the constant domain of the light chain is aligned with the first constant domain of the heavy chain, and the light chain variable domain is aligned with the variable domain of the heavy chain. Particular amino acid residues are believed to form an interface between the light and heavy chain variable domains. The light chains of antibodies from any vertebrate species can be assigned to one of two clearly distinct types, called kappa ( $\kappa$ ) and lambda ( $\lambda$ ), based on the amino acid sequences of their constant domains. Depending on the amino acid sequence of the constant domain of their heavy chains, immunoglobulins can be assigned to different classes. There are five major classes of human immunoglobulins: IgA, IgD, IgE, IgG and IgM, and several of these may be further divided into subclasses (isotypes), e.g., IgG-1, IgG-2, IgG-3, and IgG-4; IgA-1 and IgA-2. One skilled in the art would recognize the comparable classes for mouse. The heavy chain constant domains that correspond to the different classes of immunoglobulins are called alpha, delta, epsilon, gamma, and mu, respectively.

**[0103]** The term "variable" is used herein to describe certain portions of the variable domains that differ in sequence among antibodies and are used in the binding and specificity of each particular antibody for its particular antigen. However, the variability is not usually evenly distributed through the variable domains of antibodies. It is typically concentrated in three segments called complementarity determining regions (CDRs) or hypervariable regions both in the light chain and the heavy chain variable domains. The more highly conserved portions of the variable domains are called the framework (FR). The variable domains of native heavy and light chains each comprise four FR regions, largely adopting a  $\beta$ -sheet configuration, connected by three CDRs, which

form loops connecting, and in some cases forming part of, the b-sheet structure. The CDRs in each chain are held together in close proximity by the FR regions and, with the CDRs from the other chain, contribute to the formation of the antigen binding site of antibodies (see Kabat E. A. et al., "Sequences of Proteins of Immunological Interest," National Institutes of Health, Bethesda, Md. (1987)). The constant domains are not involved directly in binding an antibody to an antigen, but exhibit various effector functions, such as participation of the antibody in antibody-dependent cellular toxicity.

**[0104]** As used herein, the term "antibody or fragments thereof" encompasses chimeric antibodies and hybrid antibodies, with dual or multiple antigen or epitope specificities, and fragments, such as F(ab')<sub>2</sub>, Fab', Fab and the like, including hybrid fragments. Thus, fragments of the antibodies that retain the ability to bind their specific antigens are provided. For example, fragments of antibodies which maintain antigen binding activity are included within the meaning of the term "antibody or fragment thereof." Such antibodies and fragments can be made by techniques known in the art and can be screened for specificity and activity according to the methods set forth in the Examples and in general methods for producing antibodies and screening antibodies for specificity and activity (See Harlow and Lane. *Antibodies, A Laboratory Manual*. Cold Spring Harbor Publications, New York, (1988)).

**[0105]** Also included within the meaning of "antibody or fragments thereof" are conjugates of antibody fragments and antigen binding proteins (single chain antibodies) as described, for example, in U.S. Pat. No. 4,704,692, the contents of which are hereby incorporated by reference.

**[0106]** Optionally, the antibodies are generated in other species and "humanized" for administration in humans. Humanized forms of non-human (e.g., murine) antibodies are chimeric immunoglobulins, immunoglobulin chains or fragments thereof (such as Fv, Fab, Fab', F(ab')<sub>2</sub>, or other antigen-binding subsequences of antibodies) which contain minimal sequence derived from non-human immunoglobulin. Humanized antibodies include human immunoglobulins (recipient antibody) in which residues from a complementary determining region (CDR) of the recipient are replaced by residues from a CDR of a non-human species (donor antibody) such as mouse, rat or rabbit having the desired specificity, affinity and capacity. In some instances, Fv framework residues of the human immunoglobulin are replaced by corresponding non-human residues. Humanized antibodies may also comprise residues that are found neither in the recipient antibody nor in the imported CDR or framework sequences. In general, the humanized antibody will comprise substantially all of at least one, and typically two, variable domains, in which all or substantially all of the CDR regions correspond to those of a non-human immunoglobulin and all or substantially all of the FR regions are those of a human immunoglobulin consensus sequence. The humanized antibody optimally also will comprise at least a portion of an immunoglobulin constant region (Fc), typically that of a human immunoglobulin (Jones et al., *Nature*, 321:522-525 (1986); Riechmann et al., *Nature*, 332:323-327 (1988); and Presta, *Curr. Op. Struct. Biol.*, 2:593-596 (1992)).

**[0107]** Methods for humanizing non-human antibodies are well known in the art. Generally, a humanized antibody has one or more amino acid residues introduced into it from a source that is non-human. These non-human amino acid residues are often referred to as "import" residues, which are

typically taken from an "import" variable domain. Humanization can be essentially performed following the method of Winter and co-workers (Jones et al., *Nature*, 321:522-525 (1986); Riechmann et al., *Nature*, 332:323-327 (1988); Verhoeyen et al., *Science*, 239:1534-1536 (1988)), by substituting rodent CDRs or CDR sequences for the corresponding sequences of a human antibody. Accordingly, such "humanized" antibodies are chimeric antibodies (U.S. Pat. No. 4,816,567), wherein substantially less than an intact human variable domain has been substituted by the corresponding sequence from a non-human species. In practice, humanized antibodies are typically human antibodies in which some CDR residues and possibly some FR residues are substituted by residues from analogous sites in rodent antibodies.

**[0108]** The choice of human variable domains, both light and heavy, to be used in making the humanized antibodies is very important in order to reduce antigenicity. According to the "best-fit" method, the sequence of the variable domain of a rodent antibody is screened against the entire library of known human variable domain sequences. The human sequence which is closest to that of the rodent is then accepted as the human framework (FR) for the humanized antibody (Sims et al., *J. Immunol.*, 151:2296 (1993) and Chothia et al., *J. Mol. Biol.*, 196:901 (1987)). Another method uses a particular framework derived from the consensus sequence of all human antibodies of a particular subgroup of light or heavy chains. The same framework may be used for several different humanized antibodies (Carter et al., *Proc. Natl. Acad. Sci. USA*, 89:4285 (1992); Presta et al., *J. Immunol.*, 151:2623 (1993)).

**[0109]** It is further important that antibodies be humanized with retention of high affinity for the antigen and other favorable biological properties. To achieve this goal, according to a preferred method, humanized antibodies are prepared by a process of analysis of the parental sequences and various conceptual humanized products using three dimensional models of the parental and humanized sequences. Three dimensional immunoglobulin models are commonly available and are familiar to those skilled in the art. Computer programs are available which illustrate and display probable three-dimensional conformational structures of selected candidate immunoglobulin sequences. Inspection of these displays permits analysis of the likely role of the residues in the functioning of the candidate immunoglobulin sequence, i.e., the analysis of residues that influence the ability of the candidate immunoglobulin to bind its antigen. In this way, FR residues can be selected and combined from the consensus and import sequence so that the desired antibody characteristic, such as increased affinity for the target antigen(s), is achieved. In general, the CDR residues are directly and most substantially involved in influencing antigen binding (see, WO 94/04679, published 3 Mar. 1994).

**[0110]** Disclosed are hybridoma cells that produces the monoclonal antibody. The term "monoclonal antibody" as used herein refers to an antibody obtained from a substantially homogeneous population of antibodies, i.e., the individual antibodies comprising the population are identical except for possible naturally occurring mutations that may be present in minor amounts. The monoclonal antibodies herein specifically include "chimeric" antibodies in which a portion of the heavy and/or light chain is identical with or homologous to corresponding sequences in antibodies derived from a particular species or belonging to a particular antibody class or subclass, while the remainder of the chain(s) is identical

with or homologous to corresponding sequences in antibodies derived from another species or belonging to another antibody class or subclass, as well as fragments of such antibodies, so long as they exhibit the desired activity (See, U.S. Pat. No. 4,816,567 and Morrison et al., *Proc. Natl. Acad. Sci. USA*, 81:6851-6855 (1984)).

**[0111]** Monoclonal antibodies may be prepared using hybridoma methods, such as those described by Kohler and Milstein, *Nature*, 256:495 (1975) or Harlow and Lane. *Antibodies, A Laboratory Manual*. Cold Spring Harbor Publications, New York, (1988). In a hybridoma method, a mouse or other appropriate host animal, is typically immunized with an immunizing agent to elicit lymphocytes that produce or are capable of producing antibodies that will specifically bind to the immunizing agent. Alternatively, the lymphocytes may be immunized in vitro. Traditionally, the generation of monoclonal antibodies has depended on the availability of purified protein or peptides for use as the immunogen. More recently DNA based immunizations have shown promise as a way to elicit strong immune responses and generate monoclonal antibodies. In this approach, DNA-based immunization can be used, wherein DNA encoding a portion of an antigen expressed as a fusion protein with human IgG1 is injected into the host animal according to methods known in the art (e.g., Kilpatrick K E, et al. Gene gun delivered DNA-based immunizations mediate rapid production of murine monoclonal antibodies to the Flt-3 receptor. *Hybridoma*. 1998 December; 17(6):569-76; Kilpatrick K E et al. High-affinity monoclonal antibodies to PED/PEA-15 generated using 5 microg of DNA. *Hybridoma*. 2000 August; 19(4):297-302, which are incorporated herein by referenced in full for the the methods of antibody production) and as described in the examples.

**[0112]** An alternate approach to immunizations with either purified protein or DNA is to use antigen expressed in baculovirus. The advantages to this system include ease of generation, high levels of expression, and post-translational modifications that are highly similar to those seen in mammalian systems. Use of this system involves expressing domains of antigen-specific antibody as fusion proteins. The antigen is produced by inserting a gene fragment in-frame between the signal sequence and the mature protein domain of the antigen-specific antibody nucleotide sequence. This results in the display of the foreign proteins on the surface of the virion. This method allows immunization with whole virus, eliminating the need for purification of target antigens.

**[0113]** Generally, either peripheral blood lymphocytes ("PBLs") also referred to as peripheral blood mononuclear cells (PBMC) are used in methods of producing monoclonal antibodies if cells of human origin are desired, or spleen cells or lymph node cells are used if non-human mammalian sources are desired. The lymphocytes are then fused with an immortalized cell line using a suitable fusing agent, such as polyethylene glycol, to form a hybridoma cell (Goding, "Monoclonal Antibodies: Principles and Practice" Academic Press, (1986) pp. 59-103). Immortalized cell lines are usually transformed mammalian cells, including myeloma cells of rodent, bovine, equine, and human origin. Usually, rat or mouse myeloma cell lines are employed. The hybridoma cells may be cultured in a suitable culture medium that preferably contains one or more substances that inhibit the growth or survival of the unfused, immortalized cells. For example, if the parental cells lack the enzyme hypoxanthine guanine phosphoribosyl transferase (HGPRT or HPRT), the culture medium for the hybridomas typically will include hypoxan-

thine, aminopterin, and thymidine ("HAT medium"), which substances prevent the growth of HGPRT-deficient cells. Preferred immortalized cell lines are those that fuse efficiently, support stable high level expression of antibody by the selected antibody-producing cells, and are sensitive to a medium such as HAT medium. More preferred immortalized cell lines are murine myeloma lines, which can be obtained, for instance, from the Salk Institute Cell Distribution Center, San Diego, Calif. and the American Type Culture Collection, Rockville, Md. Human myeloma and mouse-human heteromyeloma cell lines also have been described for the production of human monoclonal antibodies (Kozbor, *J. Immunol.*, 133:3001 (1984); Brodeur et al., "Monoclonal Antibody Production Techniques and Applications" Marcel Dekker, Inc., New York, (1987) pp. 51-63). The culture medium in which the hybridoma cells are cultured can then be assayed for the presence of monoclonal antibodies directed against an antigen. Preferably, the binding specificity of monoclonal antibodies produced by the hybridoma cells is determined by immunoprecipitation or by an in vitro binding assay, such as radioimmunoassay (RIA) or enzyme-linked immunoabsorbent assay (ELISA). Such techniques and assays are known in the art, and are described further in the Examples below or in Harlow and Lane *Antibodies, A Laboratory Manual* Cold Spring Harbor Publications, New York, (1988).

**[0114]** After the desired hybridoma cells are identified, the clones may be subcloned by limiting dilution or FACS sorting procedures and grown by standard methods. Suitable culture media for this purpose include, for example, Dulbecco's Modified Eagle's Medium and RPMI-1640 medium. Alternatively, the hybridoma cells may be grown in vivo as ascites in a mammal.

**[0115]** The monoclonal antibodies secreted by the subclones may be isolated or purified from the culture medium or ascites fluid by conventional immunoglobulin purification procedures such as, for example, protein A-Sepharose, protein G, hydroxylapatite chromatography, gel electrophoresis, dialysis, or affinity chromatography.

**[0116]** The monoclonal antibodies may also be made by recombinant DNA methods, such as those described in U.S. Pat. No. 4,816,567. DNA encoding the monoclonal antibodies can be readily isolated and sequenced using conventional procedures (e.g., by using oligonucleotide probes that are capable of binding specifically to genes encoding the heavy and light chains of murine antibodies). The hybridoma cells serve as a preferred source of such DNA. Once isolated, the DNA may be placed into expression vectors, which are then transfected into host cells such as simian COS cells, Chinese hamster ovary (CHO) cells, plasmacytoma cells, or myeloma cells that do not otherwise produce immunoglobulin protein, to obtain the synthesis of monoclonal antibodies in the recombinant host cells. The DNA also may be modified, for example, by substituting the coding sequence for human heavy and light chain constant domains in place of the homologous murine sequences (U.S. Pat. No. 4,816,567) or by covalently joining to the immunoglobulin coding sequence all or part of the coding sequence for a non-immunoglobulin polypeptide.

**[0117]** In vitro methods are also suitable for preparing monovalent antibodies. Digestion of antibodies to produce fragments thereof, particularly, Fab fragments, can be accomplished using routine techniques known in the art. For instance, digestion can be performed using papain. Examples of papain digestion are described in WO 94/29348 published

Dec. 22, 1994, U.S. Pat. No. 4,342,566, and Harlow and Lane, *Antibodies, A Laboratory Manual*, Cold Spring Harbor Publications, New York, (1988). Papain digestion of antibodies typically produces two identical antigen binding fragments, called Fab fragments, each with a single antigen binding site, and a residual Fc fragment. Pepsin treatment yields a fragment, called the F(ab')<sub>2</sub> fragment, that has two antigen combining sites and is still capable of cross-linking antigen.

**[0118]** The Fab fragments produced in the antibody digestion also contain the constant domains of the light chain and the first constant domain of the heavy chain. Fab' fragments differ from Fab fragments by the addition of a few residues at the carboxy terminus of the heavy chain domain including one or more cysteines from the antibody hinge region. The F(ab')<sub>2</sub> fragment is a bivalent fragment comprising two Fab' fragments linked by a disulfide bridge at the hinge region. Fab'-SH is the designation herein for Fab' in which the cysteine residue(s) of the constant domains bear a free thiol group. Antibody fragments originally were produced as pairs of Fab' fragments which have hinge cysteines between them. Other chemical couplings of antibody fragments are also known.

**[0119]** An isolated immunogenically specific paratope or fragment of the antibody is also provided. A specific immunogenic epitope of the antibody can be isolated from the whole antibody by chemical or mechanical disruption of the molecule. The purified fragments thus obtained are tested to determine their immunogenicity and specificity by the methods taught herein. Immunoreactive paratopes of the antibody, optionally, are synthesized directly. An immunoreactive fragment is defined as an amino acid sequence of at least about two to five consecutive amino acids derived from the antibody amino acid sequence.

**[0120]** One method of producing proteins comprising the antibodies is to link two or more peptides or polypeptides together by protein chemistry techniques. For example, peptides or polypeptides can be chemically synthesized using currently available laboratory equipment using either Fmoc (9-fluorenylmethyloxycarbonyl) or Boc (tert-butyloxycarbonyl) chemistry. (Applied Biosystems, Inc., Foster City, Calif.). One skilled in the art can readily appreciate that a peptide or polypeptide corresponding to the antibody, for example, can be synthesized by standard chemical reactions. For example, a peptide or polypeptide can be synthesized and not cleaved from its synthesis resin whereas the other fragment of an antibody can be synthesized and subsequently cleaved from the resin, thereby exposing a terminal group which is functionally blocked on the other fragment. By peptide condensation reactions, these two fragments can be covalently joined via a peptide bond at their carboxyl and amino termini, respectively, to form an antibody, or fragment thereof. (Grant G A (1992) *Synthetic Peptides: A User Guide*. W.H. Freeman and Co., N.Y. (1992); Bodansky M and Trost B., Ed. (1993) *Principles of Peptide Synthesis*. Springer-Verlag Inc., NY. Alternatively, the peptide or polypeptide is independently synthesized in vivo as described above. Once isolated, these independent peptides or polypeptides may be linked to form an antibody or fragment thereof via similar peptide condensation reactions.

**[0121]** For example, enzymatic ligation of cloned or synthetic peptide segments allow relatively short peptide fragments to be joined to produce larger peptide fragments, polypeptides or whole protein domains (Abrahmsen L et al., *Biochemistry*, 30:4151 (1991)). Alternatively, native chemi-

cal ligation of synthetic peptides can be utilized to synthetically construct large peptides or polypeptides from shorter peptide fragments. This method consists of a two step chemical reaction (Dawson et al. *Synthesis of Proteins by Native Chemical Ligation*. *Science*, 266:776-779 (1994)). The first step is the chemoselective reaction of an unprotected synthetic peptide-alpha-thioester with another unprotected peptide segment containing an amino-terminal Cys residue to give a thioester-linked intermediate as the initial covalent product. Without a change in the reaction conditions, this intermediate undergoes spontaneous, rapid intramolecular reaction to form a native peptide bond at the ligation site. Application of this native chemical ligation method to the total synthesis of a protein molecule is illustrated by the preparation of human interleukin 8 (IL-8) (Baggiolini M et al. (1992) *FEBS Lett.* 307:97-101; Clark-Lewis I et al., *J. Biol. Chem.*, 269:16075 (1994); Clark-Lewis I et al., *Biochemistry*, 30:3128 (1991); Rajarathnam K et al., *Biochemistry* 33:6623-30 (1994)).

**[0122]** Alternatively, unprotected peptide segments are chemically linked where the bond formed between the peptide segments as a result of the chemical ligation is an unnatural (non-peptide) bond (Schnolzer, M et al. *Science*, 256:221 (1992)). This technique has been used to synthesize analogs of protein domains as well as large amounts of relatively pure proteins with full biological activity (deLisle Milton R C et al., *Techniques in Protein Chemistry IV*. Academic Press, New York, pp. 257-267 (1992)).

**[0123]** Also disclosed are fragments of antibodies which have bioactivity. The polypeptide fragments can be recombinant proteins obtained by cloning nucleic acids encoding the polypeptide in an expression system capable of producing the polypeptide fragments thereof, such as an adenovirus or baculovirus expression system. For example, amino acids found to not contribute to either the activity or the binding specificity or affinity of the antibody can be deleted without a loss in the respective activity. For example, in various embodiments, amino or carboxy-terminal amino acids are sequentially removed from either the native or the modified non-immunoglobulin molecule or the immunoglobulin molecule and the respective activity assayed in one of many available assays. In another example, a fragment of an antibody comprises a modified antibody wherein at least one amino acid has been substituted for the naturally occurring amino acid at a specific position, and a portion of either amino terminal or carboxy terminal amino acids, or even an internal region of the antibody, has been replaced with a polypeptide fragment or other moiety, such as biotin, which can facilitate in the purification of the modified antibody. For example, a modified antibody can be fused to a maltose binding protein, through either peptide chemistry or cloning the respective nucleic acids encoding the two polypeptide fragments into an expression vector such that the expression of the coding region results in a hybrid polypeptide. The hybrid polypeptide can be affinity purified by passing it over an amylose affinity column, and the modified antibody receptor can then be separated from the maltose binding region by cleaving the hybrid polypeptide with the specific protease factor Xa. (See, for example, New England Biolabs Product Catalog, 1996, pg. 164.). Similar purification procedures are available for isolating hybrid proteins from eukaryotic cells as well.

**[0124]** The fragments, whether attached to other sequences or not, include insertions, deletions, substitutions, or other selected modifications of particular regions or specific amino

acids residues, provided the activity of the fragment is not significantly altered or impaired compared to the nonmodified antibody or antibody fragment. These modifications can provide for some additional property, such as to remove or add amino acids capable of disulfide bonding, to increase its bio-longevity, to alter its secretory characteristics, etc. In any case, the fragment must possess a bioactive property, such as binding activity, regulation of binding at the binding domain, etc. Functional or active regions of the antibody may be identified by mutagenesis of a specific region of the protein, followed by expression and testing of the expressed polypeptide. Such methods are readily apparent to a skilled practitioner in the art and can include site-specific mutagenesis of the nucleic acid encoding the antigen. (Zoller M J et al. *Nucl. Acids Res.* 10:6487-500 (1982).

**[0125]** A variety of immunoassay formats may be used to select antibodies that selectively bind with a particular protein, variant, or fragment. For example, ELISPOT and solid-phase ELISA immunoassays are routinely used to select antibodies selectively immunoreactive with a protein, protein variant, or fragment thereof. See Harlow and Lane. *Antibodies, A Laboratory Manual*. Cold Spring Harbor Publications, New York, (1988), for a description of immunoassay formats and conditions that could be used to determine selective binding. The binding affinity of a monoclonal antibody can, for example, be determined by the Scatchard analysis of Munson et al., *Anal. Biochem.*, 107:220 (1980).

#### Compositions

**[0126]** Disclosed are the components to be used to prepare the disclosed compositions as well as the compositions themselves to be used within the methods disclosed herein. These and other materials are disclosed herein, and it is understood that when combinations, subsets, interactions, groups, etc. of these materials are disclosed that while specific reference of each various individual and collective combinations and permutation of these compounds may not be explicitly disclosed, each is specifically contemplated and described herein. For example, if a particular antigen or antibody is disclosed and discussed and a number of modifications that can be made to a number of molecules including the antigen or antibody are discussed, specifically contemplated is each and every combination and permutation of antigen or antibody and the modifications that are possible unless specifically indicated to the contrary. Thus, if a class of molecules A, B, and C are disclosed as well as a class of molecules D, E, and F and an example of a combination molecule, A-D is disclosed, then even if each is not individually recited each is individually and collectively contemplated meaning combinations, A-E, A-F, B-D, B-E, B-F, C-D, C-E, and C-F are considered disclosed. Likewise, any subset or combination of these is also disclosed. Thus, for example, the sub-group of A-E, B-F, and C-E would be considered disclosed. This concept applies to all aspects of this application including, but not limited to, steps in methods of making and using the disclosed compositions. Thus, if there are a variety of additional steps that can be performed it is understood that each of these additional steps can be performed with any specific embodiment or combination of embodiments of the disclosed methods.

**[0127]** 1. Kits

**[0128]** Disclosed herein are kits that are drawn to reagents that can be used in practicing the methods disclosed herein. The kits can include any reagent or combination of reagent discussed herein or that would be understood to be required or

beneficial in the practice of the disclosed methods. For example, the kits could include antigens to coat the wells of microtiter plates for diagnosis, efficacy, or biodetection assays embodied in some of the methods, as well as the primary antibody, and reagents required to detect the antibody as intended. It is further understood that the kit can further comprise secondary antibodies and assay support structures such as, for example, microtiter plates. For example, disclosed are kits for diagnosing the presence of a disease or exposure to an antigen in a subject comprising one or more antigens, a first antibody, and one or more reagents for detecting the presence of the first antibody. Also disclosed are kits for assessing a subject's need for further vaccination comprising an antigen, a primary antibody, a secondary antibody, a detectable agent and a microtiter plate. Also disclosed herein are kits for diagnosing the presence of a disease or condition in a subject.

**[0129]** Also provided is an antibody reagent kit comprising containers of the monoclonal antibody or fragment thereof and one or more reagents for detecting binding of the antibody or fragment thereof to an antigen. The reagents can include, for example, fluorescent tags, enzymatic tags, or other tags. The reagents can also include secondary or tertiary antibodies or reagents for enzymatic reactions, wherein the enzymatic reactions produce a product that can be visualized. The reagents can further include a microtiter plate with nitrocellulose wells.

**[0130]** It is further understood that wherein a kit may detect the presence of exposure to an antigen or diagnose the presence of disease, the kits disclosed herein can comprise one or more antigens creating a panel to target assessments. For example, the kit can be provided to assess one or more respiratory ailments, one or more diseases that can cause endocarditis, one or more diseases that can cause septic arthritis, fungi, or distinguish among hepatitis strains.

**[0131]** It is understood and herein contemplated that the kits disclosed herein can comprise any array of panels to which antigens exist. Such panels are extremely useful where the necessity to determine the causative agent of a condition will effect the treatment. Additionally, such panels can be useful in distinguishing between the presence of a line infection or blood borne infection from colonization. For example, a hospital could determine whether an entering patient had a staph infection prior to admission rather than acquired while an occupant of a hospital's facilities. Thus, also disclosed herein are methods of diagnosing a subject with a disease or exposure to an antigen (for example, an infection present in a subject prior to being admitted to a health care facility) comprising obtaining peripheral blood mononuclear cells (PBMC) from the subject and measuring the presence of antibody secreting cells (ASC) in the PBMC, wherein the presence of ASC indicates an a subject has been exposed to an antigen. Such methods can include one or more antigens on a single assay plate or assay system (including flow cytometry) such that a panel of antigens is created.

**[0132]** Panels of interest include but are not limited to Respiratory panels: to diagnose the microbial etiology of pneumonia, COPD exacerbation; Upper Respiratory Infections: which can distinguish causative organisms including but not limited to one or more of *S. pneumoniae*, *H. influenzae*, *Legionella*, *Mycoplasma*, *Moraxella*, *S. aureus*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, *E. coli*, *Chlamydia pneumoniae*, RSV, Influenza A+B, Parainfluenza, Human metapneumovirus, Rhinovirus, Coronavirus, Aden-

ovirus, SARS, TB, and Coccidiomycoses; Pediatric Otitis/respiratory panel: which can distinguish causative organisms including but not limited to one or more of *Strep pneumoniae*, *H. influenza*, *Legionella*, *Mycoplasma*, *Staph aureus*, *Moraxella*, RSV, Influenza A+B, Parainfluenza, Human metapneumovirus, Rhinovirus, Coronavirus, Adenovirus, Group A Strep, and Epstein Barr Virus (Acute Mononucleosis); Endocarditis Panel: which can distinguish causative organisms including but not limited to one or more of *Staph Aureus*, *Staph Epidermidis*, Beta hemolytic and alpha hemolytic Streptococci, Enterococcal and non-enterococcal Group D streptococcus, *Candida*, and HACEK (*Hemophilus*, *Actinobacillus*, *Cariobacterium*, *Eikenella*, and *Kingella*) organisms; Sexually Transmitted Disease (Pelvic Inflammatory Disease) Panel: which can distinguish causative organisms including but not limited to one or more of Syphilis, Gonorrhea, Chlamydia, Herpes Simplex I+II; Meningitis/Encephalitis Panel: which can distinguish causative organisms including but not limited to one or more of *Strep pneumoniae*, *Listeria*, *H influenza*, *Staph Aureus*, HSV, West Nile, Eastern Equine, Western Equine, LaCross, Jamestown canyon, St Louis, and Lymphocytic choriomeningitis virus; Septic Arthritis Panel: which can distinguish causative organisms including but not limited to one or more of Gonorrhea, *Staph Aureus*, *streptococcus*, and Coagulase negative staph; Osteomyelitis Panel: which can distinguish causative organisms including but not limited to one or more of *Staph aureus*, *Pseudomonas*, *Stenotrophomonas*, *Serratia*, *acinetobacter*, *enterobacter* sp., *E. Coli*, *Klebsiella* sp., Coagulase negative staph, *corynebacterium*, *Bacteroides fragilis*, beta hemolytic *streptococcus*, alpha hemolytic *streptococcus*, and *Enterococcus* sp.; Soft Tissue/Cellulitis Panel: which can distinguish causative organisms including but not limited to one or more of *Staph aureus*, *Pseudomonas*, *Serratia*, *acinetobacter*, *enterobacter* sp., *E. Coli*, *Klebsiella* sp., beta hemolytic *streptococcus*; Diabetic Foot Infection Panel: which can distinguish causative organisms including but not limited to one or more of *Staph aureus*, *Pseudomonas*, *Stenotrophomonas*, *Serratia*, *acinetobacter*, *enterobacter* sp., *E. Coli*, *Klebsiella* sp., Coagulase negative staph, *corynebacterium*, *Bacteroides fragilis*, beta hemolytic *streptococcus*, alpha hemolytic *streptococcus*, and *Enterococcus* sp.; Fungal pathogen vs. colonization Panel: which can distinguish causative organisms including but not limited to one or more of *Aspergillus*, *candida*, histoplasmosis, mucormycosis, and blastomycosis *coccidioides immitis*; Distinguish acute mycobacterium TB with chronic mTB; distinguish a line infection panel vs. colonization: which can distinguish causative organisms including but not limited to one or more of *Staph Aureus*, Coagulase negative staph, and *corynebacterium*; diagnosis of *staphylococcus* true line infection from blood culture contaminant; distinguish the patients with true blood borne infections compared to colonization, for example, through autolysin detection; diagnose acute Mononucleosis, or CMV panel; Hepatitis Panel: which can distinguish causative organisms including but not limited to one or more of Hepatitis A, B, C and delta; GI Abscess Panel: which can distinguish causative organisms including but not limited to one or more of Gram negative (*E. Coli*, *Pseudomonas*, *B. Fragilis*, *Enterococcus*, *Staph Aureus*; Ventilator Associated Pneumonia VAP/(Hospital Acquired Pneumonia) HAP-a diagnostic panel which can distinguish causative organisms including but not limited to one or more of *Staph Aureus*, *Pseudomonas*, *Stenotrophomonas*, *acinetobacter*, *enterobacter* sp., *E. Coli*, *Kebsiella* sp., and *serratia*

HSV; Urinary Tract Panel: which can distinguish causative organisms including but not limited to one or more of *E. Coli*, *Pseudomonas*, *enterococcus*, group B strep, *Klebsiella*, *Staph saprophyticus*, *Enterobacter* sp, and *Proteus* sp.; Pediatric Diarrhea Panel: which can distinguish causative organisms including but not limited to one or more of Rotovirus and Enterovirus; Traveler's Diarrhea Panel: which can distinguish causative organisms including but not limited to one or more of Giardia, Salmonella; Pediatric Fever Panel: HHV6, HSV, RSV, Influenza, Strep Pneumonia, and Group A strep.; and Bioterrorism panel: which can detect exposure to Anthrax, H5N1, SARS, and Smallpox.

## EXAMPLES

[0133] The following examples are put forth so as to provide those of ordinary skill in the art with a complete disclosure and description of how the compounds, compositions, articles, devices and/or methods claimed herein are made and evaluated, and are intended to be purely exemplary and are not intended to limit the disclosure. Efforts have been made to ensure accuracy with respect to numbers (e.g., amounts, temperature, etc.), but some errors and deviations should be accounted for. Unless indicated otherwise, parts are parts by weight, temperature is in ° C. or is at ambient temperature, and pressure is at or near atmospheric.

### 2. Example 1

[0134] Many vaccines induce immunological memory and establish long-term humoral protection against an infectious agent. The influenza vaccine has had mixed results depending on the similarity of the vaccine versus circulating strains. A good vaccine response induces long-term protection; however, identifying long-term responders is difficult without the tincture of time. Early biomarkers of long-term protective responses are needed especially in highly vulnerable populations such as the elderly, pregnant and immunocompromised patients.

[0135] Increase in neutralizing antibody titers is the conventional humoral immune markers of influenza vaccine responses. Antibody secreting cells (ASC) are responsible for the rise in antibody levels. Plasmablasts or ASCs are increased in the blood of human subjects after trivalent inactivated influenza (TIV) vaccination.

[0136] Trivalent influenza vaccination results in a transient burst of antigen-specific ASC in the peripheral blood, peaking at 5 to 9 days after vaccination and immediately disappearing. These cells are thought to be responsible for the 28 day rise in vaccine-specific antibody titers. While most of these plasmablasts undergo apoptosis, some migrate to the bone-marrow to become long-lived plasma cells. Identifying long-lived ASC or long-lived plasma cells subsets during this peripheral ASC burst functions as early biomarkers of long-term protective responses.

[0137] Demonstrated herein is that the influenza-specific H1 and H3 ASC Elispots can be detected 7 days post vaccination directly ex vivo from fresh and frozen peripheral blood.

### a) RESULTS

[0138] The frequency of influenza-specific ASC showed a significant increase 7 days after TIV in the peripheral blood. H1-, H3-, and H7-specific IgG ASC spots/million PBMC on day 7 were 229±341, 98±90, and 6±11 respectively. The

percentage H1-, H3-, and H7-specific of total IgG ASC spots were  $11.9 \pm 13.7$ ,  $6.3 \pm 5.8$ , and  $0.3 \pm 0.5$  respectively. Total IgG ASC spots/million PBMC pre- & 7-day post-vaccination were  $290 \pm 188$  (0.029% PBMC) and  $1691 \pm 836$  (0.17% PBMC) respectively. In contrast, no H1- and H3-specific IgG ASC were detected in any of the subjects on day 0 and 28. H7 antigens were used as negative controls.

**[0139]** H1-H3-, H7- and total specific ASC IgG ELISpot frequencies in the fresh vs frozen PBMC on day 7 were similar ( $r=0.92$ ,  $0.70$ ,  $0.4$  respectively). Frequencies of total plasmablasts by flow cytometry ( $0.21 \pm 0.19\%$  of PBMC) were similar to total IgG ASC spot frequencies suggesting most plasmablasts secreted IgG. Kinetics of influenza-specific ASC ex vivo peak on day 8 in subjects with no prior history of TIV (primary or naïve B cell response). Rise in influenza-specific ASC have double peaks on day 5 and 8 post TIV in subjects with history of TIV. The double peak may suggest an of influenza-specific ASC from memory and naïve B cells respectively. TIV-specific ASC expansion is significantly higher in one subjects with no prior history of influenza vaccination or infection. A significant rise of TIV-specific and non-TIV-specific ASC ex vivo is shown demonstrating a potential non-TIV specific or bystander ASC responses. TIV-specific ASC may be a useful early biomarker of vaccine responses.

## b) METHODS

### (1) Peripheral Blood Mononuclear Cells (PBMC) Separation:

**[0140]** PBMC were isolated by ficoll separation and some cells were frozen. Assay were performed fresh or frozen.

### (2) Antibody Secreting Cell (ASC) ELISpots

**[0141]** 96 well plates were coated with purified Influenza Hemagglutinin A from H1N1 (New Caledonia), H3N2 (Wisconsin) and H7N2 strains (Protein Science, Meriden, Conn.). Fresh or once frozen PBMCs taken at day 0, 7, or 28 from 10 young healthy subjects following TIV vaccination were incubated for 18 to 20 hours at  $37^\circ$  C. Cells were removed and alkaline-phosphatase conjugated goat-anti-human IgG (Jackson Immunoresearch) was incubated for 2 hours. Wells were developed and spots were counted using a CTL reader (Cellular Technologies Ltd).

### (3) 11-Color FACS Analysis

**[0142]** Cell analysis was performed from fresh and frozen PBMC. (CD19, CD20, CD10, CD3, CD27, IgD, IgG, CD38). Samples were analyzed by Flowjo.

### (4) Fresh vs. Frozen Study

**[0143]** Young healthy human subjects, between the ages of 19 to 32 years (mean $\pm$ SD:  $26 \pm 4$ ), without concurrent illnesses were recruited at the University of Rochester Medical Center during 2006-2007. All subjects had not received the 2006-07 trivalent influenza vaccine (TIV). Blood was collected pre, 7 & 28 days post TIV. The history of influenza vaccinations and infections were collected from each subject.

### (5) Daily Kinetics Study

**[0144]** 2 young healthy human subjects with the same criteria (see above) were recruited at the University of Rochester

Medical Center during 2006-07. Blood was collected from these subjects pre, 1 through 12, 15 and 28 days after vaccination.

### 3. Example 2

**[0145]** There is no antigen-specific ASC in the blood of healthy human subjects without evidence of antigenic exposure. 16 healthy subjects were tested and none had H1, H3 or flu vaccine ASC in the blood. They all had some baseline total IgG ASC in the blood with a frequency of  $296 \pm 148$  per million PBMC.

**[0146]** The antigen-specific ASC ex vivo in the blood after antigen exposure is short-lived approximately from day 5-15 after a single antigen dose (FIG. 5). These responses were very transient and very specific to the antigen of exposure. Thus making the presence of the antigen-specific ASC in the blood a very sensitive and very specific test to determine the antigen of exposure. The antigen-specific ASC in the blood were no longer present on day 28 post TIV.

**[0147]** However, as noted above, after single antigen exposure, antigen-specific ASC were seen in the blood directly ex vivo as early as day 5-15 (FIG. 6). FIG. 6 shows kinetics of 6 young healthy adult human subjects receiving influenza vaccine. Subjects with previous history of influenza vaccination (FIG. 6A, C, D) had lower peak TIV-specific ASC/million PBMC in the blood. Many subjects could recall a history of influenza infection however 2 of the 6 subjects could not recall a history in influenza infection (FIG. 6B, E). It is more likely these adult subjects had subclinical influenza infection. The antigen-specific ASC were very transient in these 6 subjects with variable peaks occurring differently for each subject and ranging from day 5-8. It is quite possible that previous history of flu vaccination resulted in the early rise in antigen-specific ASC responses indicating an early burst due to memory B cells as opposed to naïve B cells. The peak or the magnitude of the rise can correlate with 4 week rise of HAI or antigen-specific antibody levels. Thus, the magnitude of the antigen-specific ASC in the blood can function as an early biomarker of humoral vaccine responses. The early or late peaks can also correlate with long-term antibody levels indicating differentiation to CD138<sup>+</sup> plasma cells.

**[0148]** Moreover, the antigen-specific ASC in the blood were specific to the antigen of exposure showing no cross-reactivity with unrelated antigens. Furthermore, non-influenza samples were tested showing that the ASC ELISPOT can work with any antigen to reveal a subjects antigen specific ASC. Examples shown herein include Tetanus, influenza vaccination, acute influenza and RSV infections.

**[0149]** For example, there was a massive increase in tetanus-specific and total IgG ASC in the blood directly ex vivo of a healthy human subject 7 days after tetanus vaccination. In the same individual, there was no RSV-specific (RSV F, Ga, Gb, Hepatitis B), or influenza-specific (H1, H3 wyoming, H3 wisconsin) ASC. Additionally, there were only very few TIV-specific responses. The few TIV-specific ASC can be due to cross-reactivity with tetanus, by-stander non-specific proliferation, or nonspecific background. The H7 (an irrelevant avian strain) and BSA were negative controls.

**[0150]** Antigen-specific ASC were also evaluated directly ex vivo during an acute Respiratory Syncytial Virus (RSV) Infection. There are 2 major subtypes of RSV as identified by the RSV G protein Ga and Gb. By the age of 2, nearly all children have had RSV infection and repeat infections are common in children and adults. As an adult, antibodies to

both the Ga and Gb proteins are detected in nearly all healthy subjects. This human subject had RSV-per documented infection and RSV-specific F, Ga, and Gb ASC were detected in the blood directly ex vivo from day 5 and 12 of symptom onset. Again, this response was transient and by day 25 nearly all the antigen-specific ASC were not easily detectable. There were no TIV or influenza-specific ASC in the blood demonstrating specificity. The background ASC responses were zero.

**[0151]** Additionally, disclosed herein is the ability to diagnose acute infections with RSV-specific ASC Elispots in the blood. RSV F specific ASC were measured in the blood directly ex vivo during acute RSV infection in 18 adult outpatients during the winter of 2007-2008. Each subject had multiple time points. The acute RSV infections were documented by RSV-per from nasopharyngeal swabs. RSV-F-specific ASC responses were detected in the blood as early as day 2 of symptom onset. In some of the subjects, by day 11 the RSV-F-specific ASC responses directly ex vivo had decreased. 17/18 subjects were identified with documented per-positive RSV infection by the RSV-F specific ASC responses ex vivo.

**[0152]** RSV F specific ASC were also evaluated in the blood directly ex vivo during acute RSV infection in 22 adult hospitalized patients during the winter of 2007-2008. Many subjects had multiple time points. The acute RSV infections were documented by RSV-per from nasopharyngeal swabs. RSV-F-specific ASC responses were detected in the blood as early as day 2 of symptom onset. By day 11 the Elispot responses were still positive. Many subjects were still positive by day 28 and 33 after symptom onset. Many of these subjects were still shedding virus on day 20 of symptom onset. 18/22 subjects were identified with documented per-positive RSV infection by the RSV-F specific ASC responses ex vivo. Subjects 20378, 20345, and 20386 may have been on high dose steroids or immunocompromised. However, subject 20445 with a low level RSV-per positive test actually had no RSV-F-specific ASC in the blood but had a very high influenza-specific ASC response. Repeat RSV-per testing demonstrated negative results indicating that the RSV-F-specific ASC Elispot is more specific than the RSV-per nasal swab. In fact, of the RSV per+ subjects, the RSV-specific ASC ELISPOTs correctly diagnosed 35/39. Additionally, the RSV-specific ASC Elispots identified one false positive subject. Thus the disclosed ASC ELISPOTs are at the minimum as accurate as per testing and do not have the drawback of having a potential false positive.

**[0153]** Not only are the responses sufficiently specific to distinguish between viral and toxin ASC (Influenza and Tetanus) as well as different viral ASC (RSV and Influenza), but the ASC are specific enough to distinguish between antigen strain exposure. Antigen-specific ASC were also evaluated directly ex vivo after influenza vaccination and acute influenza infection. Again these antigen-specific ASC were tran-

sient in the blood after antigen-exposure. In the influenza vaccination, the vaccine-specific ASC were found ex vivo on day 7 after vaccination and could not be detected by day 35. In a subject with documented acute influenza A strain infection (Quikvue), influenza-specific ASC were found 6 days after symptom onset with decreasing numbers by day 8 and only a few spots detectable by day 28. The TIV-specific ASC responses was due to specificity directly to the current TIV HA strains, (A/Solomon Islands/3/2006 (H1N1), A/Wisconsin/67/2005 (H3N2), B/Malaysia/2506/2004) or due to cross-reactivity to one of these antigens.

**[0154]** Antigen-specific ASC Elispots can further identify acute influenza infections of different influenza strains (FIG. 7). The patient with acute influenza A infection probably had an H3 infection since H3 ASC elispots could only be detected ex vivo from the blood. H1-ASC responses were not detected 6, 8, or 28 days after symptom onset. The H3 Wyoming and Wisconsin H3 are very closely related. It is likely that this subject had infection with Influenza H3N2 A Brisbane since this subject received the influenza vaccine. Despite the antigenic drift between A/Wisconsin and A/Brisbane, cross-reactive epitopes were likely present. The isolated influenza A virus strain can be identified by sequence. These results were seen in two subjects with the same acute influenza A infection.

**[0155]** Traditionally ASC cells identified by flow cytometry are CD19<sup>+</sup> (or lo), CD27<sup>hi</sup>, CD38<sup>hi</sup>, IgD<sup>-</sup>. These populations were identified by flow cytometry. The frequency of the plasmablasts as identify by flow cytometry is less than 50% of the population by total IgG ASC Elispots. The total IgG ASC and antigen-specific populations were derived from several populations (plasmablasts CD27<sup>hi</sup>, CD38<sup>hi</sup> but CD138<sup>+</sup> and CD27 memory B cells). Multiple populations of CD138<sup>+</sup>, CD19<sup>+</sup> B cell subsets were sorted from 200 mL of blood from a human donor 7 days post TIV. Populations were sorted and total IgG and TIV-specific ASC Elispots were performed.

**[0156]** Total IgG ASC Elispots were detected in the following populations in the blood 7 days post-TIV: CD138<sup>+</sup> cells, ASC (plasmablasts) CD19<sup>+</sup>, CD27<sup>hi</sup>, CD38<sup>hi</sup>, IgD<sup>-</sup>, and memory CD19<sup>+</sup>CD27<sup>+</sup>, IgD<sup>-</sup>, with a few in the double negative CD19<sup>+</sup>CD27<sup>-</sup>IgD<sup>-</sup> B cell populations. No total IgG ASC Elispots were detected in the naïve or the unswitched memory populations. The antigen-specific TIV-specific ASC were found in the following populations: CD138<sup>+</sup> cells, ASC (plasmablasts) CD19<sup>+</sup>, CD27<sup>hi</sup>, CD38<sup>hi</sup>, IgD<sup>-</sup>, and memory CD19<sup>+</sup>CD27<sup>+</sup>, IgD<sup>-</sup>, with a few in the double negative CD19<sup>+</sup>CD27<sup>-</sup>IgD<sup>-</sup> B cells (Table 1). Thus, the cell populations responsible for the antigen-specificity of ASC in the blood with vaccination include: blood plasma cells (CD138<sup>+</sup>), plasmablasts (CD19<sup>+</sup>IgD<sup>-</sup> CD27<sup>hi</sup>CD38<sup>hi</sup>), memory B cells (CD19<sup>+</sup>, IgD<sup>-</sup>CD27<sup>+</sup>).

TOTAL ACTUAL numbers from TOTAL PBMC		1500 ± 275		1040 ± 204	0.69

[0157] Antigen-specific ASC were detectable in many healthy subjects not currently vaccinated or infected. All adult subjects had RSV infection multiple times. All adult subjects had clinical or subclinical influenza infection as adults. RSV-specific ASC can be detected in the human bone marrow from long-lived plasma cells. The influenza-specific ASC can also be found in healthy human bone marrow from long lived plasma cells.

[0158] These Antigen-specific ASC are very specific and sensitive. The same antigen-specific ASC was detected in bone marrow but not in blood of the same subject at day 0. Using this assay an increase in the TIV-specific ASC can be detected in the blood directly ex vivo after influenza vaccination. TIV-specific ASC could not be detected in the same subject in the blood at day 28 after vaccination. At week 17 after vaccination, the same frequency of TIV-specific per 1000 IgG producing CD 138<sup>+</sup> cells were detected. Explanations for this include: (1) no increase in long-lived plasma cells post TIV; (2) equal rise of total IgG CD138<sup>+</sup> cells and flu-specific IgG producers; (3) sensitivity limits of the assay to detect minute differences in antigen-specific CD138<sup>+</sup> responses; (4) apoptosis and replacement of old TIV-specific CD138<sup>+</sup> ASC plasma cells in the bone marrow after vaccination with new immigrants; and/or (5) no new immigrant TIV-specific ASC into the marrow.

What is claimed is:

1. A method of assessing the efficacy of a vaccine in a subject comprising obtaining peripheral blood mononuclear cells (PBMC) from the subject between 5 and 15 days following administration of the vaccine, measuring the number of antibody secreting cells (ASC) in the PBMC, and comparing the number of ASC to a standard, wherein more ASC in the PBMC relative to a standard indicates an efficacious vaccine.

2. A method of assessing the need of the administration of a booster immunization in a subject comprising obtaining peripheral blood mononuclear cells (PBMC) from the subject between 5 and 15 days following administration of a vaccine, measuring the number of antibody secreting cells (ASC) in the PBMC, and comparing the number of ASC to a standard, wherein fewer ASC in the PBMC relative to a standard indicates the need for an immunization boost.

3. The method of claim 2, wherein the PBMC are obtained 5 days following administration of a vaccine.

4. The method of claim 2, wherein the PBMC are obtained 7 days following administration of a vaccine.

5. The method of claim 2, wherein the number of ASC is determined by an immunoassay.

6. The method of claim 5, wherein the immunoassay is an ELISPOT assay.

7. The method of claim 6, wherein the ELISPOT assay is antigen specific.

8. The method of claim 2, wherein the ASC are long-lived ASC.

9. The method of claim 2, wherein the vaccine is directed against a viral antigen selected from the group of viruses consisting of Herpes Simplex virus-1, Herpes Simplex virus-2, Varicella-Zoster virus, Epstein-Barr virus, Cytomegalovirus, Human Herpes virus-6, Variola virus, Vesicular stomatitis virus, Hepatitis A virus, Hepatitis B virus, Hepatitis C virus, Hepatitis D virus, Hepatitis E virus, Rhinovirus, Coronavirus, Influenza virus A, Influenza virus B, Measles virus, Polyomavirus, Human Papillomavirus, Respiratory syncytial virus, Adenovirus, Coxsackie virus, Dengue virus, Mumps virus, Poliovirus, Rabies virus, Rous sarcoma virus, Reovirus, Yellow fever virus, Ebola virus, Marburg virus, Lassa fever virus, Eastern Equine Encephalitis virus, Japanese Encephalitis virus, St. Louis Encephalitis virus, Murray Valley fever virus, West Nile virus, Rift Valley fever virus, Rotavirus A, Rotavirus B, Rotavirus C, Sindbis virus, Simian Immunodeficiency virus, Human T-cell Leukemia virus type-1, Hantavirus, Rubella virus, Simian Immunodeficiency virus, Human Immunodeficiency virus type-1, and Human Immunodeficiency virus type-2.

10. The method of claim 2, wherein the vaccine is directed against a bacterial antigen selected from the group of bacterium consisting of *M. tuberculosis*, *M. bovis*, *M. bovis* strain BCG, BCG substrains, *M. avium*, *M. intracellulare*, *M. africanum*, *M. kansasii*, *M. marinum*, *M. ulcerans*, *M. avium* subspecies *paratuberculosis*, *Nocardia asteroides*, other *Nocardia* species, *Legionella pneumophila*, other *Legionella* species, *Salmonella typhi*, other *Salmonella* species, *Shigella* species, *Yersinia pestis*, *Pasteurella haemolytica*, *Pasteurella multocida*, other *Pasteurella* species, *Actinobacillus pleuropneumoniae*, *Listeria monocytogenes*, *Listeria ivanovii*, *Brucella abortus*, other *Brucella* species, *Cowdria ruminantium*, *Chlamydia pneumoniae*, *Chlamydia trachomatis*, *Chlamydia psittaci*, *Coxiella burnetii*, other *Rickettsial* species, *Ehrlichia* species, *Staphylococcus aureus*, *Staphylococcus epidermidis*, *Streptococcus pyogenes*, *Streptococcus agalactiae*, *Bacillus anthracis*, *Escherichia coli*, *Vibrio cholerae*, *Campylobacter* species, *Neisseria meningitidis*, *Neisseria gonorrhoea*, *Pseudomonas aeruginosa*, other *Pseudomonas* species, *Haemophilus influenzae*, *Haemophilus ducreyi*,

other *Hemophilus* species, *Clostridium tetani*, other *Clostridium* species, *Yersinia enterocolitica*, and other *Yersinia* species.

**11.** A method of determining antigen exposure in a subject comprising obtaining peripheral blood mononuclear cells (PBMC) from the subject and measuring the presence of antibody secreting cells (ASC) in the PBMC, wherein the presence of ASC indicates antigen exposure.

**12.** The method of claim **11**, wherein the presence of ASC is determined by immunoassay.

**13.** The method of claim **11**, wherein the immunoassay is an ELISPOT assay.

**14.** The method of claim **11**, wherein the antigen is a vaccine.

**15.** The method of claim **11**, wherein the antigen is a bio-warfare agent.

**16.** The method of claim **11**, wherein the antigen is a toxin.

**17.** The method of claim **16**, wherein the toxin is selected from the group consisting of Abrin, Conotoxins Diacetoxyscirpenol Bovine spongiform encephalopathy agent, Ricin, Saxitoxin, Tetrodotoxin, epsilon toxin, Botulinum neurotox-

ins, Shigatoxin, Staphylococcal enterotoxins, T-2 toxin, Diphtheria toxin, Tetanus toxoid, and pertussis toxin.

**18.** A method of assessing the effectiveness of a therapy for an autoimmune disease comprising obtaining peripheral blood mononuclear cells (PBMC) from the subject and measuring the presence of antibody secreting cells (ASC) in the PBMC, wherein the absence of ASC indicates an effective therapy.

**19.** A kit for diagnosing the presence of a disease or exposure to an antigen in a subject comprising one or more antigens, a first antibody, and one or more reagents for detecting the presence of the first antibody.

**20.** A method for diagnosing the presence of a disease or exposure to an antigen in a subject comprising obtaining peripheral blood mononuclear cells (PBMC) from the subject and using the kit of claim **19** to measure the presence of antibody secreting cells (ASC) in the PBMC, wherein the presence of ASC indicates an a subject has been is infected with or has been exposed to an antigen.
